The roots of many plants contain sugar. The Beet-Root is extensively cultivated in Germany and France for the purpose of yielding sugar. The Turnip, the Carrot, and the Parsnip, are familiar instances of roots which contain sugar, and which owe their principal dietetical value to this circumstance. The roots of many plants eaten by animals contain sugar, and are probably sought after on this account. Most of the plants belonging to the natural family of Grasses contain sugar. The *Saccharum officinarum* is the principal source of the sugar that is used dietetically in Great Britain. It is contained in its tissues at almost all seasons of its growth, but it is present in especially large quantities previous to flowering; it is at this stage that the sap is employed for the manufacture of sugar. The Indian Corn (*Zea Mays*) yields a sufficient quantity of sugar to render it a profitable source of manufacture in the United States of America. Barley, oats, wheat, rye, and rice, all contain sugar in their stems, and might be cultivated for this purpose were they not more valuable as producers of grain. The dietetical value of grasses on which cattle and horses are fed depends in a great measure on the quantity of sugar they contain.

Many of the Palm Tribe yield sugar in their sap. The *Caryota urens*, *Cocos nucifera*, and species of *Sagus*, are used in tropical countries for obtaining sugar.

Another source of sugar in the vegetable kingdom is the Fruit. Nearly all the fruits of plants eaten by man contain sugar. Such are the grape, the orange, the pine-apple, pear, and numerous others.

The different species of sugar have the following composition:—

1. Milk-Sugar $C_{12}H_{22}O_{11} + 5H_2O$
2. Cane-Sugar $C_{12}H_{22}O_{11} + 2H_2O$
3. Grape-Sugar $C_{12}H_{22}O_{11} + 2H_2O$
4. Eucalyptus-Sugar $C_{12}H_{22}O_{11} + 9H_2O$

Milk-Sugar is an integral constituent of the milk of the *Mammalia*, and has very rarely been met with anywhere else. It has been said to have been detected in eggs during the process of incubation; but this observation requires to be confirmed. Cane-Sugar is the most closely related to starch and dextrine, differing from them merely by one equivalent of water. It is not by any means so widely distributed as Grape-Sugar, being found in very few plants besides the sugar-cane, beet, and maple. Grape-Sugar is identical with the sugar in honey and in diabetic urine, and with the Glucose or fruit-sugar of the French chemists. The uncrystallisable sugar which is obtained during the decomposition of many plants, and which is yielded by starch acted on by diastase or sulphuric acid, has the same composition as Grape-Sugar. Cane-Sugar is not fermentable. The only fermentable form of sugar is Grape-Sugar; and in all cases where alcohol is formed, the substances employed must pass into the form of Grape-Sugar.

Eucalyptus-Sugar is a species of manna produced in Van Diemen's Land by various species of *Eucalyptus*. Whether it is the natural sap spontaneously escaping, or whether it is the sap extracted by the locust and afterwards excreted, is uncertain. Its properties have been carefully examined by Professor Johnstone.

There is obviously an intimate connection between these different kinds of sugar, as well as between cellulose, starch, dextrine, and gum. They all contain carbon, in combination with the elements of water.

As they all contain C_{12} or a multiple of it, they are produced from each other by a simple change depending on catalytic force.

If sulphuric acid is allowed to act on gelatin, a species of sugar containing nitrogen, and termed Glycicoll or gelatin sugar, is formed. Its formula is $C_6H_7N_2O_7$; and it is worthy of remark, that if from two of its equivalents we deduct one equivalent of cane-sugar, we obtain the elements of two equivalents of urea, or—

This relation leads to the belief that sugar is a component part of the gelatinous tissues, and when separated from them it may be presumed to discharge the same functions as when either cane- or grape-sugar is supplied with the food. In other words, there exists in the substances yielding gelatin a primary matter which exists also in cane-sugar. If then substances or tissues containing gelatin are employed in effecting the metamorphosis continually occurring in the animal body, this primary matter may serve the same purpose as cane-sugar when supplied to feed the body. On these grounds Mulder considers that gelatin-sugar should be classed amongst the nourishing substances. If gelatin be formed in the animal body, then sugar, either derived directly from the food or produced from starch in the alimentary canal, may be used for this purpose.

It is not known in what part of the plant sugar is formed. Mr. Knight states that birch sap contains more sugar the farther from the root it is collected; this seems to prove that the sap, which probably contains much dextrine, is changed into sugar as it passes through the cell-walls. When sugar accumulates in certain parts of a plant, it almost always remains in solution; it is however found crystallised in some few instances, as in the nectary of *Fritillaria imperialis*.

Closely allied in its chemical composition to sugar is a peculiar substance to which the term Mucilage is given. Although insoluble in water, it assumes the appearance of a mucilaginous mass when immersed in that fluid. It sometimes accumulates largely in certain parts of plants, as in the perisperm of quince-seed, lint-seed, &c.; it is the chief constituent of the gums tragacanth and Bassora, and is abundant in various roots, as for instance the mallows. According to Mulder's analysis it must be represented by the formula $C_{24}H_{40}O_{19}$. It has been shown by Schmidt that mucilage when digested with dilute sulphuric acid is converted into sugar. Hence it supplies a link to the following series of analogous substances:—

Grape-Sugar and Fruit-Sugar	$C_{12}H_{22}O_{11}$
Cellulose and Soluble Inulin	$C_{24}H_{40}O_{19}$
Starch, Dextrin, Gum, Insoluble Inulin, and Lichen-Starch	$C_{24}H_{40}O_{19}$
Mucilage, Milk-Sugar, and Eucalyptus-Sugar	$C_{24}H_{40}O_{19}$
Cane-Sugar	$C_{12}H_{22}O_{11}$

In its physical characters, the product of the mucous membrane of the animal body resembles vegetable mucilage. Owing to their insolubility in water, both these substances serve to cover denuded parts of animals, and thus they are both suited to lessen or prevent the influence of acrid matters on the tender parts of the animal frame. It is for this reason that the mucilage of salep, tragacanth, &c., may be made, in certain diseased conditions, to supply temporarily the want of animal mucus. In chemical composition they are perfectly distinct, as animal mucus contains nitrogen. The mucus of the animal body seems however to differ according to the organs by which it is produced. (Day's edition of Simon's 'Animal Chemistry,' vol. ii. p. 78, note.)

SUGAR-CANE. [SACCHARUM.]

SUGAR-SQUIRREL. [MARSUPIATA.]

SUIDÆ, a family of Pachydermatous Animals, including the various forms of Swine.

The Swine have on each foot two large principal toes shod with stout hoofs, and two lateral toes which are much shorter and hardly touch the earth. The incisor teeth are variable in number, but the lower incisors are all levelled forwards. The canines are projected from the mouth and recurved upwards. The muzzle is terminated by a truncated snout fitted for turning up the ground, and the stomach is but little divided.

Cuvier remarks that the skull of a hog is nearly a quadrangular pyramid, the palatine surface of which is almost perpendicular to the base, represented by the occiput. The nasal bones occupy the upper part of the muzzle; their base is slightly widened; the other extremity advances a little pointedly above the nasal aperture. The intermaxillaries ascend rather obliquely to one-third of the length of the nasal bones, and carry at their extremity the peculiar bone which supports the snout. The orbit is round, and well defined (cerné) by an advance of the frontal and the two post-orbital apophyses; the portion formed by the frontal especially is well marked. Between the two it is nearly the sixth of a circle, not closed. The frontals descend in front of the orbit more than a fourth of the length of the muzzle before they encounter the nasal bones. The lachrymal bone occupies a rather large rhomboidal space upon the cheek. The two lachrymal holes are pierced, the upper one on the border itself, the other a little in front of the border of the orbit. In the orbit, the lachrymal descends to the upper border of the vault of the sub-orbital canal. The jugal bone is articulated to the whole width of the lachrymal bone. It is elevated, and the suture with the temporal bone behind the post-orbital

apophysis descends at first, and afterwards becomes horizontal. The zygomatic apophysis of the temporal bone ascends a little, and rises to a point backwards above the auditory meatus. The temple is well marked by a parietal crest, which goes to the occiput without touching its congener; so that the occiput is truncated squarely above, where it widens a little. The palate is prolonged a little behind the origin of the zygomatic arches. The palatine bone advances no farther than just before the last molar tooth. It is prolonged a little on each side, where it terminates in form of a tubercle between the two pterygoid wings. It ascends into the orbit, showing nothing there but a process (languette) by no means large, which pushes forward into the internal walls of the suborbital canal. The internal pterygoid apophyses are distinct from the body of the bone, high and narrow, and terminated in a hook. The external apophyses at least equal them, make one with the body of the bone, and also terminate in a hook. In the temple the posterior sphenoid is nearly reduced to the anterior surface of the external pterygoid apophyses. It articulates itself with the temporal bone, does not touch the frontal except with its point, and does not reach the parietal. The anterior part occupies most space there, and it permits nevertheless the frontal bone to descend in front of it till it reaches the palatine, and even to bend itself back to enter into the vault of the suborbital canal between the maxillary and the palatine bones. The temporal bone raises itself rather high in the temple, where its parietal suture curves downwards. It occupies a part of the occiput on each side, and its suture comes in front of the base of the mastoid apophysis, which is very long, very pointed, and entirely belonging to the occipital bone. The tympanic cavity (caisse) is a very projecting tubercle, not to say pointed, in front of this apophysis.

Skull of Hog, seen from above. (Cuvier.)

Skull of Hog, seen in profile. (Cuvier.)

It receives a very long and very narrow auditory meatus, which commences very high behind the posterior base of the arcade. Its cavity is very small, and the whole of its apparent volume consists only of cellular osseous substance. The glenoid facet is projecting, and much wider than it is long, between the arcade and the tympanic cavity, which last is early ossified in its convex portion, and seemed to Cuvier to belong to the temporal bone, from which it is not separated even in the fetus, but the petrous bone (rocher) is long distinguishable: this last does not appear externally. The two frontal bones unite together early, and the two parietals still earlier: there is no interparietal in those subjects which have seen the light. The suborbital hole is rather large, above the fourth molar, nearly in the middle of the maxillary bone. Its canal opens widely in the orbit, at the ordinary place. The lachrymal holes have been already noticed. There is below the orbital surface of the orbital bone a deep hollow without issue, the use of which was unknown to Cuvier. At the upper vault of the orbit is a suborbital hole, which conducts to an aperture pierced on the front. The orbital hole is near the suture with the anterior sphenoid. The analogous holes to the sphenoid and pterygo-palatine bones are in the suborbital canal. The last enters the palate opposite the penultimate molar. The optic and sphenoid-orbital holes are approximated as ordinarily, and rather large. The oval aperture is separated by the whole external pterygoid apophysis, the direction of which is transversal. It is common to the sphenoid and temporal bones, and is only separated by a small bony ridge from a large carotidian hole, which answers in part to the internal side of the tympanic cavity. Under the junction

of the anterior sphenoid to the posterior is a double canal, which goes into the thickness of the vomer. The posterior foramen lacernum, the stylo-mastoidian, and the condyloidian, are very much approximated near the mastoid apophysis. At the interior one may see that the frontal and sphenoidal sinuses are very much extended, and narrow the cerebral cavity a good deal. The first-named sinuses extend to the occiput. The sella ascends nearly vertically to sustain the optic nerves. The bony tentorium only exists on the sides; it does no more than pass upon the petrous bone. The ethmoidal fossæ is very much sunk, of moderate size, divided by a very salient crest, and riddled with numerous holes. The area of the cerebral cavity is only half that of the cranium, as it appears externally, so much is it augmented by the great sinuses which exist even to the occiput.

Different *Suidæ* offer more or less variations in the length of the head.

The Wild Boar (*Sus Scrofa*, Linn.) has the face longer and the skull less elevated; the domestic pig of Europe has the cranium slightly more elevated, and the face still sufficiently long; the Siamese Pig has the face shorter, the cranium more convex in the frontal region, and larger in proportion.

The Masked Boar of Africa differs from the European boar in having its zygomata extending more outwards and taking a more horizontal direction, and especially by a great elevated apophysis, above the alveolus of the canine tooth, and ascending obliquely so as to leave a canal between it and the maxillary bone. It terminates by a great rugged tubercle, and the nasal bone opposite to a similar tubercle. It is to these two prominences that the great warts or mamillæ, which give this animal so hideous an aspect, adhere.

The Babyrussa, or Babiroussa, when compared with a Siamese Hog of the same size, has the cranium longer in proportion to the muzzle, the orbit more advanced, the temporal fossæ more approximated on the cranium, the zygomatic arch longer and ascending less suddenly backwards, and the tympanic cavities much longer.

Skull of Babyrussa.

The peculiar character of the Ethiopian Boar (*Phacochoerus*) consists in the retreat of the eyes and the relative smallness of the temporal fossæ, the necessary consequence of that retreat; in the enormous development of the base of the zygomatic arches; and in the width of that part, as well as in the interval between the orbits. The alveoli of its enormous canines form a projection on each side of the muzzle, which is terminated by two small peculiar bones that unite the extremities of the nasal to those of the intermaxillary bones, and which correspond to the single bone carried on the extremity of the intermaxillaries in the Common Hog. The tympanic cavities are small, terminated in a point. The basilar part has between them a hook projecting on each side, and in front are two very deep and very remarkable fossæ prolonging the vault of the back nostrils, and hollowed principally in the sphenoid bone.

The Peccary approximates more to the Babyrussa than to the Siamese Hog, but its muzzle is still shorter; the tympanic cavities are rounded and cellular; its mastoid apophyses are very short and directed backwards; its palate is prolonged, narrowing as it retires, more backward than its molars. Its glenoid facet is very different from that of the hog, and fenced (cercée) in front and behind as in some of the *Carnivora*.

Cuvier remarks that the relationship of the *Suidæ* with the *Carnivora* is very close, indeed that there is no difference in the anterior part of the cranium. Take, says he, the head of an Opossum (*Sarigue*) for example; shorten the cranium; widen the orbits and parietal crests; raise the occiput, shortening at the same time the basilar part and the back nostrils, and you will only require the differences of projection of some parts, the presence of an external pterygoid apophysis, the direction downwards of the curvature of the zygomatic arch, &c., to arrive at the head of a Hog. In the pterygoidian and neighbouring parts, the Kangaroo approaches it still nearer.

The dentition of the hog has its characters and laws, like that of all other animals. The normal number of its teeth is six incisors—

two canines, and fourteen molar teeth in each jaw. ('Ossements Fossiles.')

Teeth of Hog. (F. Cuvier.)

The extremities of the hog have much relationship to those of the Ruminants [RUMINANTIA], especially of the Sheep and the Stag.

The Spine of the Shoulder-Blade, as in the Horse, is nearly at an equal distance from the anterior and posterior border; whilst in the Ox and Stag it is much nearer to the anterior edge. This spine, as in the Horse again, is lowered before, and more projecting at its upper third, where it forms a hook bent backwards. In other respects, it is wider in the upper part than that of the Horse, its coracoid tubercle is less projecting, and its articular surface higher than it is wide. The great tuberosity of the Humerus is very high, as in the Ruminants; but it is notched by a large re-entering arch; theicipital groove is, on the internal side, narrower and deeper; the whole upper part of the head of the bone is narrower in proportion. The Ulna is wide and depressed, with a ridge on its anterior surface, forming with the internal edge a long hollow surface, by which in advancing age it is soldered to the radius. In the Ruminants it is more compressed and much more slender. In the Peccary it is soldered sooner and more completely than in the Hog. The Carpus much resembles that of Ruminants, with this difference, that the trapezoidal remains a longer time distinct from the great bone. Nevertheless, no bone has a perfect resemblance, and on comparison the difference will be detected, although it cannot be expressed in words.

The differences of the Femora are also very difficult to be expressed verbally. The head is more elevated and more convex towards the upper part than that of any Ruminant. The great trochanter is wider and a little notched; the projecting ridge which goes from one to the other trochanter is more rounded; the internal edge of the rotular pulley ascends less than the other, which is the contrary of the structure in the Ruminants; the notch between the condyles is narrower and pointed forwards, &c. The Tibia is easily recognised, because it is shorter, has its lower head squared and not narrowed from behind forwards, and has no articulation with the fibula. The principal difference of the Tarsus rests on the small wedge-shaped bone, on the vestige of the fifth toe, and in the scaphoid remaining distinct from the cuboid bone. The astragalus tends to that of the Ruminants by the form of the pulley of the lower head. The metacarpal bones, metatarsals, and toes, cannot be confounded with those of any other animal, and their characters, partly visible externally, are known to all naturalists, or will be easily defined by them. It need only be remarked, that in the Peccary the two middle bones of the metacarpus and metatarsus are soldered into a Cannon, as in the Ruminants, and that the only vestige in this animal of the external toe on the hind foot is a small flattened stylet, applied against the base of the cannon bone.

The Cervical Vertebrae of the Hog are not easily confounded with NAT. HIST. DIV. VOL. IV.

those of any Ruminant of its proportions, by reason of the brevity of their bodies, and the width of their transverse apophyses, especially of those of the penultimate one. The body of the vertebra is not so convex in front as in the Ruminants. ('Ossements Fossiles.')

The number of the vertebrae appears to be liable to considerable variation. (Eyton, 'Proc. of Zool. Society,' 1837.)

The other parts of the internal organisation of the Suidæ need no detailed description. In the Museum of the College of Surgeons in London is a preparation of the stomach of *Dicotyles torquatus*, which is remarkable for having three compartments.

Linnaeus placed the genus *Sus* between *Hippopotamus* and *Rhinoceros*, in his order *Bellua*, which order stands between those of *Pecora* and *Cete*, in his last edition of the 'Systema Naturæ.'

Cuvier arranges the Cochons (*Sus*, Linn.) under his ordinary *Pachydermata*. This genus comprises the sub-genera *Sus*, *Phacocharus*, and *Dicotyles*, and stands between *Hippopotamus* and *Anoplotherium*, which last is followed by *Rhinoceros*.

Illiger arranges *Sus* as the only genus of his *Setigera*, his last family of his fifth order *Multungula*, which order is immediately preceded by the *Nasuta*, consisting of the genus *Tapirus*. The *Solidungula* immediately follow the *Multungula*.

Dr. J. E. Gray makes the *Suina* a sub-family of the *Elephantida*. He includes in it the following species, of which specimens exist in the British Museum:—

Sus fasciatus, the Striped Boar.

S. Scrofa, the Boar.

S. Papuensis, the Bêne.

S. Indicus, the Indian Wild Boar.

Babirusa Alfurus, the Babirusa.

Choirepotamus Africamus, the Bosch-Vark.

Phacocharus Ethiopicus, the Valke-Vark, or Emgallo.

P. Aliani, the Haruja, or Hallup.

Dicotyles Tajaqu, the Peccary, or Tajaqu.

D. labiatus, the Tagnicate.

We now proceed to give some account of the more remarkable forms in this list.

Sus Scrofa, Linn., *S. Aper*, Briss., the Wild Boar, Le Sanglier of the French, is still an inhabitant of many of the temperate parts of Europe and Asia, but no longer exists in a natural state in the British Islands.

Dental Formula:—Incisors, $\frac{6}{6}$; Canines, $\frac{1-1}{1-1}$; Molars, $\frac{7-7}{7-7} = 44$.

The Wild Boar, which is too well known to need description, and of which living individuals are to be seen in the gardens of the Zoological Society, Regent's Park, harbours in the most solitary places in retired forests. His lair is generally in some wild and remote spot, not far from water, and commanding by some devious path access to the open country. The young, or Marcellans, as they are termed by the French, are striped with longitudinal bands.

Throughout Europe the boar was held in high estimation as a beast of chase. Nobles, princes, and even kings, delighted to take the field with the boar-spear, and peril their persons in hunting this fierce animal. In our own country, where it formerly rioted in the dense forests which have now vanished before the inroads of an increasing population, the loss of his eyes was the punishment inflicted by William the Conqueror on him who was convicted of killing a wild boar. In the vast forest which so late as Henry II.'s time stood on the north side of London, were stags, fallow-deer, wild boars, and bulls. In the 'Leges Wallicæ' it appears that Howel-dda gave permission to his grand huntsman to chase the boar from the middle of November to the beginning of December. In Europe the boar-spear has given way to the rifle; but in India, where the field is taken on horseback, the spear is still used, and hog-hunting appears to be one of the most exciting of the wild sports of that land of the sun.

An attempt was made by Charles I. to restore this noble game to England, and he turned out several wild boars in the New Forest; but the civil wars were no friendly times for the experiment, and they were all destroyed. More recently General Howe procured some wild boars and sows from Germany, and turned them into the forests of Walmer and Alice Holt, or Ayles Holt, "to the great terror of the neighbourhood," as White says, in his 'History of Selborne;' "and, at one time, a wild bull or buffalo: but the country rose upon them, and destroyed them."

The senses of the Hog are acute, especially that of smelling. The broad snout ploughs up the herbage; and not a root, an insect, or a worm, escapes the olfactory sense. If fairly treated, it is by no means a dirty animal; but it is too often stied up in its own filth. There are few more pleasing scenes in the farm-yard than a well laid-out piggery properly kept. The animal itself is anything but stupid, and is capable of strong attachment where kindness is shown to it. That it is docile the number of learned pigs proves; and still more the famous sporting sow, that went regularly out with the gun, and stood her game as staunch as any pointer. It is said that the Hog is trained on the Continent to hunt for truffles. [HOG, in ARTS AND SC. DIV.]

Babirusa, F. Cuv.—F. Cuvier has separated this form from *Sus*, relying upon characters, one of the principal of which is the upward

direction of the alveolus of the upper canine tooth, which is enormously developed, ascending upwards, and curving back upon itself; the first upper grinding-tooth is a false molar, and the first two below have the same character. The canines of the lower jaw form long, and, as compared with the other tusked *Suidæ*, slender tusks, as the animal advances in age.

Dental Formula:—Incisors, $\frac{4}{4}$; Canines, $\frac{1-1}{1-1}$; Molars, $\frac{5-5}{5-5} = 32$.

Teeth of *Babirusa*.

B. Alfurus, the Babirusa; *Sus Babirusa* of Linnæus; Le Babyronsa of Buffon; Le Sanglier des Indes Orientales of Brisson; and Le Cochon Cerf of Lesson and other French authors.

The Babirusa stands high upon its rather slender legs. The skin, which is of a grayish tint, inclining to fawn-colour on the belly, is very thinly furnished with hair. The upper tusks come through the skin of the muzzle, and form nearly a circle directed backwards, often touching the skin again on their downward curvature. The females are smaller than the males, and are without these tusks.

Babirusa, male. (From an individual in the Gardens of the Zoological Society of London.)

Piso, in his edition of the 'Natural and Medical History of East India,' by Bontius, remarks, that sedulous as Bontius was, he had made no mention of this animal. Piso however supplies the deficiency, and gives in the page no very bad figures of the animal and of its skull. In the frontispiece however, where the Babirusa occupies a conspicuous place in the foreground, the painter has evidently had the Hog-Deer in his mind, and has taken a few liberties with the animal's muzzle, aspect, and bearing, though the tusks are tolerably correct, lengthening its neck not a little. The Indians, Piso tells us, ascribe these animals to a union of the Hog and the Deer. He says that they are only found in the Island of Bourou, 30 miles distant from Amboyna. He adds, that the Babirusa is swift and fierce, and that its flesh is highly prized (*inter delicias expetita*) by both natives and foreigners.

It still inhabits the marshy forests of the island of Bonrou, and is said to be abundant in the Moluccas, and a few other islands of the Indian Archipelago.

F. Cuvier has given very good figures, and a lively description of two males and females brought to France in the Astrolabe, and kept in the Paris Menagerie. The female was much younger and more active than the male, which was aged and very fat, and spent his short life in eating, drinking, and sleeping. The female bred once after her arrival in Europe. When the male retired to rest she would cover him completely over with litter, and then creep in under the straw to him, so that both were concealed from sight. They died of diseased lungs about three years after their arrival.

The lower tusks must be formidable weapons, though not so destructive as those of some of the other *Suidæ*. In old individuals the upper tusks can hardly inflict a wound: they may perhaps ward off the bushes from the eyes of the animal as it rushes through the thick cover of its retreats.

Head of *Babirusa*, seen in profile. *a*, male; *b*, female.

Sus Papuensis, the Bène of the natives of New Guinea, is described as being remarkable for its small stature and its agreeable and slender form. The canines of the upper jaw are very small, and nearly of the same form as the incisors; the bristles are rather thick, short, yellow, and brownish below, white above and annulated with black; the tail is very short. The young (Marcassins) are of a brown colour, more or less deep, with five rather bright fulvous stripes upon the back.

The length of the Papuan Hog is three feet. It is common in the forests of New Guinea, and the Papuans highly esteem its flesh, which the French found excellent. The natives catch the young in the woods in order to rear them in a kind of domestication.

M. Lesson remarks that the *S. Papuensis* has many points of analogy with the Peccaries, and seems to be intermediate between them and the True Hogs.

Phacocharus (*Phascocharus*, F. Cuvier).—Feet formed like those of the True Hogs; two triquetrous incisors above, six small ones below; tusks lateral and directed upwards, very large; molars composed of enamelled cylinders inclosing the osseous substance and joined together by a cortical substance; very large fleshy warts or wens on the cheeks; tail short.

Incisors, $\frac{2 \text{ or } 0}{6 \text{ or } 0}$; Canines, $\frac{1-1}{1-1}$; Molars, $\frac{3-3}{3-3} = 16 \text{ or } 24$.

F. Cuvier remarks that we have here arrived at a system of dentition entirely different from that of the True Hogs (Sangliers), and which announces animals endowed with a particular nature, and much more herbivorous than omnivorous. Nevertheless, in the locomotive organs the True Hogs and the Phacocharus bear the greatest resemblance to each other, and have accordingly been united in the same genus, as far as these organs served for the principal basis of the formation of generic groups. At present, he observes, but two Phacocharus are known, and one has incisors, whilst the other appears to be deprived of them. We have seen, he remarks, that in the Pachyderms there is but little regularity in the number of the teeth; and he inquires whether this may belong to the nature of these animals, or to lacunæ which it has not been given to us to fill up; a question which he will not decide. Therefore he does not separate these animals.

F. Cuvier's plate is taken, as far as regards the upper jaw, from a Phacocharus without incisors, and, as relates to the lower jaw, from a Phacocharus furnished with those teeth; and he remarks that the discs of the last molars of the first are smaller and less numerous than those of the last molar of the second; he concludes by inquiring whether this may be a specific character.

P. Eliani, Elian's Wart-Hog, is a native of the North of Africa. It is at all ages provided with incisors in the upper and lower jaw, and therefore is in the most marked manner distinguished from the Wart-Hog of the Cape. Another distinction is, that the Cape Wart-Hog has, according to F. Cuvier, only three molars in the upper and lower jaws; whereas, *P. Eliani* always presents four in the upper jaw. But there ought to be hesitation in admitting this last mark of distinction to be of much weight, because the anterior molars are disposed to decay.

Further, if a line be drawn from the hind part of the head, as far as the most prominent part of the nasal-bone, there will be found in *P. Eliani* a sinus, the depression of which falls in the middle of the line. This very place, in the case of the Wart-Hog of the Cape, rises to an arched prominence; and there are other differences.

The skin is of an earthy colour, scantily bristled. A mane which extends along the neck and the back arises between the ears; the single hairs of it are frequently 10 inches long. All the bristles, those of the mane included, are light-brown. They have not each a

Teeth of *Phacocharus*.

a, last molar tooth, side view. (F. Cuvier.)

separate root, but three or six bristles form one tuft, and have one common root. The whole body, with the exception of the back, appears rather hare. The head is broad along the brow, which is rather depressed; the eyes are small, and situated very high up; there is a depression below the eyes, and near the cheek is a wart, which, as compared with a smaller one alongside the cheek, may be called the larger wart. These warts are formed of thickened skinny tissue, and they are smaller than in the species from the Cape. A whisker of white hair curling upwards runs along the lower edge of the lower jaw. The eyes are small, eye-lashes blackish, eye-brow bristles long and black, and under the eyes is a tuft of bristles. Ears cut obliquely at the lower part of the external edge, and the whole margin bordered with white bristly hair. Tail nearly hare, thin, and with a tuft of hair. On the fore feet a piece of thick hard protuberant skin.

Wart-Hog (*Phacocharus Ailiani*). (Rüppell.)

This species was found by M. Rüppell, first in Kordofan, and more frequently afterwards on the eastern slope of Abyssinia. It haunts

low hushes and forests. It creeps on its bent fore feet in quest of food, and in this posture digs up the roots of plants (of which its food is supposed to consist) with its enormous canine teeth. The hind legs push the body forward as it moves in this posture.

P. Aethiopicus, the Black Bark, or African Wart-Hog, differs from the last in the larger size of its warts, and the more singular form of its head. Some fine specimens are now living (1855) in the Gardens of the Zoological Society, Regent's Park.

Dicotyles, Cuv.—Intermediate toes larger than in *Sus*, and touching the ground. Canines of the ordinary form, not protruding from the mouth. Incisors and molars resembling those of *Sus*. A glandular opening on the loins, secreting a fetid humour. No tail. The two great bones of the metacarpus and those of the metatarsus united together.

Dental Formula :—Incisors, $\frac{4}{6}$; Canines, $\frac{1-1}{1-1}$; Molars, $\frac{6-6}{6-6} = 38$.

Teeth of *Dicotyles*. (F. Cuvier.)

Of this form, now so well known by means of our zoological societies and publications, there are two species, *D. torquatus* and *D. labiatus*.

D. torquatus, The Collared Peccary. In Hernandez we find a figure and two descriptions of this species under the names of Quauhtla Coymatl, Quapizotl, *Aper Mexicanus*, by which 'Jo. Fabri Lyncei Descriptio' is headed; and of Coyamatl, or Quauhcoyamatl, 'quoniam est montanus,' by Fernandez. Both notice the gland on the loins; and the latter, who repeats the Mexican names first above stated, remarks that it is fierce and truculent when first taken, but mild when tamed, "et amicus domesticis, habeturque in deliciis." The flesh he describes as similar to ordinary pork, but bolder and not so sweet, and the food of the animal as consisting of acorns, roots, "and other mountain fruits," as well as of worms, earthworms, and other creatures of the same sort that are bred in lacustrine, moist, and marshy places. These Mexican Hogs, he adds, lay waste the cultivated fields, if they are not driven from them, go in droves, and when domesticated are fed on the same esculents as the Common Hogs.

The Collared Peccary has been bred in a state of domestication in South America and in some of the West Indian Islands; but, notwithstanding the favourable accounts given of its flesh by the author whom we have last quoted, it is out of all comparison inferior to that of the Common Hog, both in flavour and fatness. The comparative infertility, too, of the Peccary, which only produces two young at a birth, is at once a bar to its superseding the domestic pig, which is equally fertile in all climates where it has been introduced. The gland, too, is highly objectionable, making the animal, neat and trim as it

generally is, a nuisance in life, and flavouring the flesh, unless removed immediately after death. D'Azara however seems to have revelled in its scent as a perfume; and Tyson and others appear to have considered it agreeable enough. Those which we have seen in captivity have been positively offensive; and the Peccaries seem to have affected the olfactory organs of Buffon, Sonnini, and indeed all other modern authors, in the same disagreeable way. This species is the Patira of Sonnini, and the Taytétou of D'Azara, according to Mr. Bennett.

It is found in Mexico and nearly the whole of South America, where they haunt the thickest and greatest forests, dwelling in hollows of trees or earths made by other animals. Not common in the vicinity of villages, to which they are bad neighbours, devastating the crops of maize, potatoes, sugar-canes, and manihot.

D. labiatus, the White-Lipped Peccary. D'Azara appears to be the first who distinguished the two species of Peccaries, which are both confounded by Linneus under the common name of *Sus Tajaçu*. Indeed the old writers above quoted seem to have fallen into the same error; for it is very improbable that the Collared Peccary only was known when they wrote. Cuvier, who first gave the scientific specific names now used, states that *Dicotyles labiatus* is the Taytétou, Tajaçu, &c., as well as the Tagnicati of Azara. It is larger than the Collared Peccary, which is seldom more than three feet long, and rarely weighs more than 50 lbs.; whereas the White-Lipped Peccary often measures three feet and a half in length, and sometimes weighs 100 lbs. The last-named species is thicker and stouter, the legs are shorter, and the snout, which is longer, has its termination more expanded. Its prevailing hue is brown, and the lips are white.

The secretion from the gland in this species has been said to be inodorous. This could not be said of the White-Lipped Peccaries exhibited in the Gardens of the Zoological Society of London, though they were perhaps somewhat less offensive than the Collared Peccaries.

Mr. Bennett says, "unlike the former species, the White-Lipped Peccaries congregate in numerous bands, sometimes amounting, it is said, to more than a thousand individuals of all ages. Thus united they frequently traverse extensive districts, the whole troop occupying an extent of a league in length, and directed in their march, if the accounts of the natives are to be credited, by a leader, who takes his station at the head of the foremost rank. Should they be impeded in their progress by a river, the chief stops for a moment, and then plunges boldly into the stream, and is followed by all the rest of the troop. The breadth of the river or the rapidity of the current appears to be but trifling obstacles in their way, and to be overcome with the greatest facility. On reaching the opposite bank, they proceed directly on their course, and continue their march even through the plantations which, unfortunately for the owners, may happen to lie in their way; and which they sometimes completely devastate by rooting in the ground for their favourite food, or devouring such fruit as they find there. If they meet with anything unusual on their way, they make a terrific clattering with their teeth, and stop and examine the object of their alarm. When they have ascertained that there is no danger, they continue their route without further delay; but if a huntsman should venture to attack them when they are thus assembled in large numbers, he is sure to be surrounded by multitudes, and torn to pieces by their tusks, if he is so unwise as to neglect his only chance of escape, which consists in climbing a tree, and thus getting fairly out of their reach. The smaller bands are by no means equally courageous, and always take to flight at the first attack."

Mr. Lesson remarks that this species have been nowhere more particularly observed than in Paraguay.

In Guyana, Sonnini was surrounded by a herd of Peccaries, exasperated at the havoc made among them by the fusils of himself and his companions. Betaking himself to a tree, he beheld at his ease how they encouraged, by their grunts and rubbing snouts together, those which were wounded from the shots above, still maintaining their ground with bristles erect and eyes fiery with rage. They sometimes stood an incessant fusillade of two or three hours before they quitted the battle-field and left their dead to the conquerors. After such encounters comes the festival of the travellers. A great gridiron, so to speak, of sticks fixed in the ground, and some three feet in height, with numerous small branches laid on it in a transverse direction, is got ready. On this sylvan cooking-apparatus the pieces of Peccary pork are broiled over a slow fire kept up during the night. Sonnini dwells enthusiastically on these forest feasts, to which he looks back with regret.

Specimens of the *Choiropotamus Africanus* are now living (1855) in the Gardens of the Zoological Society, Regent's Park.

Fossil remains of this family have been found in the second division (Miocene of Lyell) and the third and fourth divisions (Pliocene of Lyell) of the tertiary deposits. In the first of these divisions are to be noticed the three species of *Sus* found in the Epplesheim sand. Bones of swine occur frequently in the bone-caverns and bone-breccia.

SULA, a genus of Natatorial Birds belonging to the family *Pelecanidae*. [PELECANIDÆ.] It has the following characters:—Bill strong, long, forming an elongated cone very large at its base, compressed towards the point, which is slightly curved; edges of the mandibles serrated; the angle of the gape behind the line of the eyes. Face and throat naked; nostrils basal, linear, hidden. Legs short, strong, placed rather backward; three toes in front, one behind articulated

to the inner surface of the tarsus, all four toes united by membrane; claw of the middle toe pectinated. Wings long, first quill-feather the longest. Tail cuneiform.

S. alba, the Gannet, or Solan Goose, Fou de Bassan of the French. It is the *S. Bassan* of many authors. This bird is a constant resident on the British coast. It breeds in large numbers at Lundy Island, off the coast of Devon, the west of Ireland, the Isle of Ailsa, and the Bass Rock in the Frith of Forth.

They form their nests in a mass of weeds and grass. They lay one egg. Gannets feed exclusively on fish.

The Gannet is found in the Baltic, on the west coast of Norway, at the Faroe Islands, and Iceland. On the coasts of America they are found from Labrador to Carolina. It is also included in the birds of Madeira and South Africa.

In the adult bird the bill is of a horny grayish-white; the edges serrated, the naked skin of the face blue; iris of a pale straw-colour; the head and neck buff-colour; all the rest of the plumage white, except the wing primaries, which are black; the line of the bones of the legs and toes in front green, the other portions of the bones and the connecting membranes almost black. The whole length of the bird is about 34 inches, from the breast to the end of the first quill-feather, which is the longest, 19 inches. The young have the appearance of the young of the Red-Throated Diver, but the structure of the foot will prevent them from being taken for each other.

(Yarrell, *History of British Birds*.)

SULCULEOLARIA. [ACALPHEÆ.]

SULPHUR, an elementary substance, occurring abundantly in an uncombined form on the surface of the earth. It occurs also in combination with various metals, forming sulphurets and sulphates (iron, copper, lead, mercury).

Native Sulphur is found in acute octahedrons, and, secondary to this form, with imperfect octahedral cleavage. It also occurs massive. The colour and streak of sulphur is yellow, sometimes orange-yellow; lustre vitreous. Transparent to translucent. Hardness 1.5 to 2.5. Specific gravity 2.07. It is easily distinguished by burning blue, and emitting a sulphur odour.

The great repositories of sulphur are either beds of gypsum and the associated rocks, or the regions of active or extinct volcanoes. In the valley of Noto and Mazzaro in Sicily, at Conil near Cadiz in Spain, Bex in Switzerland, and Cracow in Poland, it occurs in the former situation. Sicily and the neighbouring volcanic islands, Vesuvius and the Solfatara in its vicinity, Iceland, Tenerife, Java, Hawaii, New Zealand, Deception Island, and most active volcanic regions, afford more or less sulphur. The native sulphur of commerce is brought mostly from Sicily, where it occurs in beds along the central part of the south coast and to some distance inland. It is often associated with fine crystals of sulphate of strontian. It undergoes rough purification by fusion before exportation, which separates the earth and clay with which it occurs. Sixteen or seventeen thousand tons are annually imported from Sicily into England alone. Sulphur is also exported from the crater of Vulcano, one of the Lipari Islands, and from the Solfatara near Naples.

It is also found in the United States of America, on the Potomac, and in districts where sulphuretted hydrogen is evolved from mineral springs.

Sulphuric Acid is said to occur in the waters of the Rio Viuagro in South America, also in Java, and at Lake de Taal or Luzon in the East Indies. Sulphuric acid has been detected in the fumes of volcanoes.

(Dana *Manual of Mineralogy*.)

SULPHUR-WORT. [PEUCEDANUM.]

SUMACH. [RHUS.]

SUN-BIRDS. [CINNYRIDÆ.]

SUN-DEW. [DROSERÆ.]

SUN-FISH. [ORTHOGORISCUS.]

SUN-FLOWER, the English name of a genus of Plants called *Helianthus*, from *ἥλιος*, the sun, and *ἄθος*, a flower. Two reasons have been assigned for giving the plants of this genus this name: first, the resemblance of the large disc and ray of their flowers to the sun; and second, the tendency of these flowers, in a stronger degree than in other plants, to present their face to the sun. From this circumstance, the French Tournesol, Italian Girasole, and English Turnsol have been given. This is a genus consisting of very stately herbaceous plants, and containing upwards of 40 species, all of which are indigenous to America. It belongs to the natural order *Compositæ*, and has the following characters:—Head composed of many flowers, the flowers of the ray being ligulate and neuter, the flowers of the disc tubular and hermaphrodite; involucre irregularly imbricated, the outer scales foliaceous, the inner ones scaly; receptacle plane or convex, covered with oblong acute scales; tube of the corolla of discoid flowers short, 5-toothed; style appendiculated. Fruit an achium compressed laterally; pappus in the form of two lanceolate acute deciduous scales. The leaves are opposite, sometimes superiorly alternate, and either entire or toothed. The whole plant is scabrous or villous. The flowers are solitary, and of a yellow or orange colour.

H. annuus, Annual Sun-Flower, is an herbaceous annual plant with thick rough stems from 6 to 20 feet in height; leaves alternate, petiolate, nearly heart-shaped, crenulated or dentated, rough. The

heads are large, from one to two feet in diameter, and composed of a multitude of flowers of a beautiful yellow colour, terminal, solitary, inclined, the disc vertical and oftenest facing the south. This species is the largest of the genus. It is indigenous in Mexico and Peru; it was early introduced into Europe after the discovery of America, and has since been very generally cultivated in gardens, on account of its very large and handsome yellow flowers. The plant however in Europe never attains the height nor the flowers the size they do in their native soil and climate. The albumen of the seeds of this plant contains a large quantity of oil; and it has been proposed to cultivate it for the sake of obtaining this oil, which is very palatable, and might be used for the table. Cows and oxen, horses, sheep, pigs, rabbits, and poultry are all fond of it. When torrifed in the same manner as the seeds of coffee they make an agreeable drink, which may be used as a substitute for that article.

H. multiflorus, Many-Flowered Sun-Flower, is not so high a plant as the last, nor are its flowers so large. It has vivacious roots, which produce numerous herbaceous stems, which are branched and rough; its leaves are alternate, petiolate, dentated, the inferior ones are heart-shaped, the superior oval and acuminate; the heads of flowers are numerous and not inclined. It is a native of Virginia.

H. tuberosus, Tuberous Sun-Flower, or Jerusalem Artichoke. This latter name is a barbarous corruption of the Italian Girasole, this species having been introduced into Europe at the Farnese Garden at Rome, whence it was originally distributed. The roots are composed of a number of oblong tubercles, very large and fleshy, reddish outside and white within, resembling a potato; the stems are herbaceous and upright; the leaves are alternate and opposite, petiolate, oval, rough; the heads of flowers are yellow, and small compared with the two preceding species. It is a native of Brazil. In France it is also known by the name of Topinambour and Poire de Terre. According to Braconnot and Payen, the tubers do not contain fecula, but a vegetable principle called Inulin or Dahlin. These tubers, when cooked, form a good substitute for potatoes, and by some are even preferred.

Some of the species secrete a resinous juice, which is found to exude from the various organs of the plant. This is most observable in the *H. thurifer*, in which the resinous matter runs down the stem. This is sometimes observed to occur in the flowers of *H. annuus*. The *H. indicus* of Linnaeus and our gardens is probably only a variety of *H. annuus*, and is not a native of India, as its name would imply. This last species, according to Dr. Royle, is cultivated by the natives of India for the purpose of obtaining oil from its seeds.

SUN-ROSE. [HELIANTHEMUM.]

SUN-STONE. [FELSAP.]

SURF-DUCK. [DUCKS.]

SURIANACEÆ, the name given to a supposed order of Plants represented by a solitary species, *Suriana maritima*, found on the coast of all tropical countries. It is a woody plant, with alternate leaves without stipules; hairs capitate, pointed. Flowers racemose; calyx 5-parted, slightly imbricated; petals the like number, equal, shortly clawed; stamens indefinite, hypogynous, placed in a single row; filaments subulate, anthers roundish, incumbent, bursting internally by two longitudinal fissures; carpels 5, distinct, attached to a very short gynobase, 1-celled, with two ascending collateral ovules; styles rising from near the base of the carpels; stigmas simple; pericarp woody. Seed solitary, erect, compressed. In some respects it may be compared with *Coriariaceæ* and *Cranesbills*, but its annular embryo is so peculiar as to indicate a somewhat different relationship; and this indeed has led Dr. Wight to suggest an affinity to *Phytolacacæ*.

(Lindley, *Vegetable Kingdom*.)

SURIRELLA. [DIATOMACEÆ.]

SURINIA. [STRIGIDÆ.]

SUZANNITE, *Sulphato-Tricarbonate of Lead*, a Mineral occurring crystallised in two forms, namely, an acute rhomboid and a right rhombic prism. Cleavage of both forms perpendicular to the axis, and very distinct. Colour white, gray, pale-yellow, or green. Streak white. Hardness 2.5. Transparent, translucent. Specific gravity 6.2 to 6.4. It is found at Lead-Hills, in Scotland. Its analysis by Brooke gives—

Carbonate of Lead	72.5
Sulphate of Lead	27.5
	—100

SWALLOW-HAWK. [FALCONIDÆ.]

SWALLOW TRIBE, *Hirundinidæ*, a family of Insectivorous Birds, in which the powers of flight are very highly developed, but which have the feet comparatively weak.

Belon placed the Swallows at the end of his birds, immediately following his Petit Mouchet, or Moineau de Haye, which is engraved with a fly in its mouth. Brisson arranges the Swallow, together with the Goat-Sucker [CAPRIMULGIDÆ] in his eighth order, consisting of birds which have the bill very small, compressed horizontally at its base, and hooked at its end, its aperture being larger than the head. This order stands between that containing *Upupa* and *Promerops* and that containing *Tangara* and the Finches.

The genus *Hirundo* is placed, in the twelfth edition of the 'Systema Nature,' between *Caprimulgus* and *Pipra*, in the second division of the *Passeres*, namely, *Curvirostres*, 'mandibul. superior, apice incurvata.'

In Latham's method it also appears in the second section of the *Passeres*, which is characterised much in the same way. In Lacépède's arrangement, *Hirundo* and *Caprimulgus* form his third order of birds (first sub-class and first sub-division) with 'Bec très court,' standing between the antecedent order, consisting of those with the 'Bec droit et menu' (the last genus of which is *Motacilla*) and the succeeding one, comprising birds with 'Bec arqué,' the first genus of which is *Glaucopsis*. M. Duméril arranges the Swallows in his sixth family (*Planirostres* or *Omalorampes*) of the *Passeres*. Meyer's *Chelidonæ* (his sixth order) consist of *Hirundo*, *Cypselus*, and *Caprimulgus*. The same genera appear in Illiger's method as his family *Hiantes*, the last of his order *Ambulatoræ*. In Cuvier's system the Swallows and Goatsuckers, including *Podargus*, form his family *Fissirostres*, which stands between the *Dentirostres* and *Conirostres*. M. Vieillot's *Chelidonæ* are placed between his *Baccivores* and his *Myothères*, in his second tribe (*Anisodactyli*). M. Temminck's eighth order, embracing the Swallows and Goatsuckers, stands between the orders consisting of the Kingfishers and the Pigeons. In M. Latreille's method the first genus of the first family (*Latirostræ*) of his second order (*Passereaux*) contains the Goatsuckers and Swallows.

Mr. Vigors states that the families which compose the first tribe (*Fissirostres*) of his second order (*Insectores*) are distinguished from those of all the other, except the *Tenuirostres*, by their habit of feeding on the wing. From the latter, or the Suctorial Birds, which meet them at one of the extremes of the tribe, and of which the typical families feed also on the wing, they are distinguished, he observes, by their animal food, which they take by their bills or in the gape of their mouths; while the *Tenuirostres* live chiefly upon vegetable juices, which they extract with their tongue. "The *Fissirostres*," says Mr. Vigors in continuation, "depending so much on the powers of their wings, exhibit a proportional deficiency in the strength of their legs. These members are not only shorter and weaker than in the other *Perchers* (the typical families of the *Tenuirostres* here again being excepted, which correspond with them in this particular also), but they have their external toes in general to such a degree united with the internal, for the most part as far as to the second phalanx, that they are deprived of the free play of the joint; and the bird is thus rendered nearly incapable of using its legs in walking, or for any purpose besides that of mere perching. But even in this particular a group of the typical family appears deficient; for the toes of the genus *Cypselus*, being all placed in front, seem to assist the bird only in suspending itself, where other birds would perch. All the families of the tribe are again united by a striking conformity in their mode of nidification. They deviate from the manners of the *Perchers* in general in forming their nests on the ground; or if, like some of the *Hirundinidæ*, they choose elevated situations for that purpose, they build up the exterior of their nests with earth cemented into a solid substance, and thus preserve a similarity in their construction to those nests which are actually formed on the ground. The two typical groups of this tribe may be observed to be separated from the other three by the shortness of their bills and the wider gape of the mouth. Their mode of seizing their prey is conformable to these characters: they receive it in full flight into the cavity of their mouths, which remain open for that purpose, and where a viscous exudation within, and a strong reticulated fence of vibrissæ on the exterior, assist in securing the victim: while, on the other hand, the longer-billed families catch their food by their bills. The series of succession in the tribe may be stated as follows, the typical families being placed in the centre:—

"*Meropidæ*.
Hirundinidæ.
Caprimulgidæ.
Todidæ.
Halcyonidæ."

After alluding to the approximation between the *Meropidæ* and *Hirundinidæ*, Mr. Vigors notices the union between the latter and the *Caprimulgidæ*. [CAPRIMULGIDÆ.]

Prince Bonaparte arranges the *Hirundinidæ* as the second family of the *Passeres*; and in the first section of that family (*Ambulatoræ*). The following are the Prince's sub-families and genera:—

a. *Cypselinæ*.

Genera:—*Cypselus*, Ill.; *Chaturæ*, Sw.

b. *Hirundinidæ*.

Genera:—*Pronge*, Boie; *Chelidon*, Boie; *Cotyle*, Boie; and *Hirundo*, Linn. (*Cecropis*, Boie). The family stands between the *Caprimulgidæ* and the *Amelidæ*.

Mr. G. R. Gray divides the *Fissirostres*, into two sub-tribes:—1. *Fissirostres Nocturnæ*, consisting of the family *Caprimulgidæ*, with its sub-families; and, 2. *Fissirostres Diurnæ*, the first family of which last sub-tribe is *Hirundinidæ*, with the following sub-families:—

1. *Cypselinæ*.

Genera:—*Cypselus*, Ill. (*Apus*, Scop.; *Micropus*, W. and Mey.; *Hirundo*, L.); *Macropteryx*, Sw. (*Macropterus*, Sw.), *Hemiprocnes* Nitzsch., *Acanthylis*, Boie (*Chaturæ*, Steph.; *Hirundo*, L.), *Collocalia*, G. R. Gray (*Hirundo*, L.).

2. *Hirundininae*.

Genera:—*Hirundo*, L. (*Cecropis*, Boie), *Progne*, Boie (*Hirundo*, Gm.) *Cotyle*, Boie (*Hirundo*, L.), *Chelidon*, Boie (*Hirundo*, Vieill.)

The European species of this family are the Swift (*Cypselus Apus*, C. murarius, Temm.); the White-Bellied or Great Gibraltar Swift (*Cypselus Melba*, C. *Alpinus*, Temm.); the Rock-Martin (*Hirundo rupestris*); the Rufous Swallow (*Hirundo rufula*, Temm.); the Chimney Swallow (*Hirundo rustica*, Linn.); the Martin (*Hirundo urbana*, Linn.); and the Sand-Martin (*Hirundo riparia*, Linn.). Of these the first and the three last are British (summer visitors); and of the second, three specimens have been killed, and one found dead in Britain. (Yarrell.) [HIRUNDINIDÆ.]

Cypselus.—Tarsus thickly feathered; all the four toes directed forwards; the two middle equal; the hallux, or inner toe, shorter than the exterior; tail forked or even. (Sw.)

Head and Foot of Common Swift. (Swainson.)

C. Apus, the Common Swift, which usually comes to this country from Africa early in May, and leaves us generally by the middle of August, is the Moutardier, Martelet, Martinet noir ou Grand Martinet of the French; Rondone, Dini, and Dardano of the Italians; Ring-Swala of the Swedes; Thurm Schwalbe of the Germans; Gier Zwaluw of the Netherlands; Screech, Screech Martin, Deviling, Screamer, and Black Martin of the country-people in various parts of Britain; and Martin Dû of the Welsh.

Belon considers this to be the *Ἀπὸς* and *Κυφέλλος*, or *Κυφέλος* of Aristotle ('Hist. Anim.' ix. 30); and indeed Aristotle states that it would be difficult to distinguish these *ἀπὸς* or *κυφέλλος* from Swallows (*Χελιδόνες*), if it were not that the former had the log covered with feathers (*δαρείαν*). M. Camus however thinks that those zoologists who are of opinion that Aristotle had here the Swifts in view are wrong; for the latter says (loc. cit.) that the birds thus designated by him made long nests of mud, with only just room enough to enter, which, M. Camus remarks, Swifts do not, but House-Martins do; and therefore he thinks the birds last named are meant.

In White's 'History of Selbourne' will be found many highly interesting particulars relating to the habits of the Swift, especially with regard to the structure of the nest, its constant use (by the same birds, as has been proved in some instances) for years in succession, and the treatment of the young by the parents under certain circumstances. Mr. Salmon has verified the fact of their producing three, and sometimes even four eggs, though two appear to be the ordinary number.

The old quatrain, in the 'Portraits d'Oyseaux,' sums up the qualities of the Swift thus:—

"Le Moutardier, ou bien grand Martinet,
Est à voler très-leger et fort viste;
Mais sur la terre il ne pose, ny giste;
Car y estant, sur pieds mobile n'est."

The bird appears to spread over Europe in the summer and breeding season. They visit Lapland, Norway, Denmark, and Sweden; in which last country Professor Nilsson states that it makes its nest in hollows of trees in the woods. Its eastward range appears to be as far as the mountain-lake Baikal. At Erzerum it has been observed in numbers from May till September. Mr. Yarrell states that he has never seen this species in any collection brought from India. It has been noted at Madeira. Montagu extends its southward range in Africa as far as the Cape: Temminck limits it to the tropics. In our own country it has been remarked that Swifts are less plentiful with us than they formerly were.

The genus *Hirundo* is represented in Britain by three species. [HIRUNDINIDÆ.] The following is a summary of the characters of the Martin, or House-Martin (*H. urbana*):—

"Ce Martinet fait en forme spherique
Son nid si fort, qu'Impossible est de mieux,
En l'attachant aux bastiments fort vieux;
Duquel l'entrée est estroite et oblique."

H. esculenta, is the Swallow which makes the edible nests that form a considerable article of Chinese commerce. The species, which is the Lawet of the Javanese, is small. It is brown above, and whitish beneath and at the end of the tail, which last is forked. The nests are made of a particular species of *Fucus* [ALGÆ] which the bird macerates and bruises before it employs the material in layers so as to form the whitish gelatinous cup-shaped nests so highly prized as delicacies and restoratives by the Chinese when dissolved in their soups. Bontius, who seems to have thought that the nest was formed of no vegetable material, says of these birds, "ex spuma maris basin scopulorum allentis, tenacem quandam materiam colligunt, sive ca-

Balanarum seu aliorum picinum sit acmen, ex qua nidos suos edificunt, in iisque ova ponunt, et pullos excludunt." The nests are affixed to the rocks, and the finest are semi-transparent. Coarse or dirty nests are used for glue, but the good ones are eagerly sought after. "Chinenses hos nidos e scopulis avulsos, ingenti quantitate per Indiam venales ferunt, gulosis in summas delicias, qui eos galline, seu vervecis decocto dissolutos, avidè devorant, et ostrea, fungis, et cæteris gulis irritamentis, longè anteponunt." This recipe for making the famous birds'-nest soup ends a chapter which begins poetically and pathetically with the following lines:—

"Quid scopulorum, Progne, quid inhospita littora nidis
Optas, per medias hos gula queret aquas!"

There is another species, *H. fuciphaga*, the Linchi of the Javanese, about five inches long, nearly an inch shorter than *H. esculenta*, which has a white abdomen and longer wings in proportion to its size. This species constructs its nests of mosses and lichens connected by the same glutinous substance which composes the edible nest of *H. esculenta*. Dr. Horsfield, who states this in his 'Systematic Arrangement and Description of Birds from the Island of Java' ('Linn. Trans.' vol. xiii.), there remarks that the specimens of *H. esculenta* examined by him in Java and those which he brought home differ from Latham's description in being uniformly of a blackish-colour without a white extremity to the rectrices. Bontius, who gives a rude cut of the nests adhering to the rock, with the birds sitting and approaching, describes his birds, in the chapter 'De nidis hirundinum edulibus,' above referred to, as 'Aviculæ parvæ discoloræ, hirundinum specie.' Specimens of *H. esculenta* and *H. fuciphaga* are preserved in the Museum of the East India Company.

H. Senegalensis. It is the Senegal Swallow of authors; Le Grande Hirondelle à Ventre Ronx de Senegal. Large. Tail forked. Plumage above glossy-black; sides of the nape and neck, and lower part of the back, rufous; beneath ferruginous, verging to white on the throat and breast; under wing-coverts and thighs pure white. (Sw.)

Mr. Swainson, who has given a most characteristic figure of this species in his 'Birds of Western Africa,' observes that this is the largest of the true swallows that he has yet seen, for it measures full eight inches in its total length. "Its structure," says that observing author, "is precisely similar to our common *H. rustica*, excepting that the hind toe and claw, which in that bird is of equal length with the shank, is in this a slight degree longer. In the general cast of its colouring it has such a close resemblance to the *H. Capensis* figured by Le Vaillant as an inhabitant of the Cape of Good Hope ('Ois. d'Afr.' 5, pl. 245, fig. 1), that we were at first tempted to believe it was the same, particularly as Le Vaillant forgets to give us the size of his bird, an omission which all the compilers since his days have perpetuated. It appears however that the Cape species has a small white spot on the inner web of all the lateral tail-feathers, excepting that which is elongated, and that the feathers of the vent have a black stripe down the middle of each." In the same volume will be found a description of the small but very beautiful White-Bodied Swallow, *H. leucosoma*, Sw.

The species of *Hirundines* enumerated by Nuttall, in his interesting 'Manual of the Ornithology of the United States and Canada,' are, the Purple Martin (*Progne purpurea*, Boie; *H. purpurea*, Linn.), the Barn-Swallow (*H. rufa*, Gm.; *H. Americana*, Wils.), the Fulvous or Cliff-Swallow (*H. fulva*, Vieill.; *H. lunifrons*, Say), the White-Bellied Swallow (*Chelidon bicolor*, Bonap.; *H. bicolor*, Vieill.; *H. viridis*, Wils.), the Bank-Swallow or Sand-Martin (*Cotyle riparia* (L.) Boie; *H. riparia*, Wils.), and the Chimney Swift or Swallow (*Chaturus Pelagius*, Steph.; *Cypselus Pelagius*, Temm.; *H. Pelagius*, Linn., Wils.).

H. purpurea, the Purple Martin. The male is dark bluish glossy purple; the wings and forked tail are brownish-black. The female and young are bluish-brown, and have the belly whitish. Tail considerably forked. Length about 8 inches. Alar extent 16 inches.

"This beautiful species," says Nuttall, "like many others of the family, seeks out the dwellings of man, associating himself equally with the master and the slave, the colonist and the aboriginal. To him it is indifferent whether his mansion be carved and painted, or huddled into the hospitable shed of the calabash or gourd. Secure of an asylum for his mate and young, while under the protection of man, he twitters forth his gratitude, and is everywhere welcomed to a home. So eager is he to claim this kind of protection, that sometimes he ventures hostilities with the blue birds and domestic pigeons, whom he often forces to abandon their hereditary claims. Satisfied with their reception and success, like so many contented and faithful domestics, they return year after year to the same station."

The Chimney-Swift, or Swallow, is sooty-brown, and has the chin and line over the eye of a dull whitish. It is about 4½ inches in length, but 12 in alar extent. The wings extend far beyond the tail, which is even, and, like that of the rest of the genus, mucronate.

H. fasciata, Latham, is L'Hirondelle à Ceinture Blanche of Buffon, the White-Bellied Swallow of Latham. It is of a glossy blue-black; thighs and band on the abdomen snowy.

Mr. Swainson speaks of this as a very rare bird; and, according to Buffon, it is sometimes seen perched on floating trees in the rivers of Guyana. Length to the end of the deeply-forked tail about 6 inches. The first quill is longest.

White-Bellied Swallow (*Hirundo fasciata*). (Swainson, 'Zool. Ill.,' 2nd series.)

Macropteryx.—Tarsus remarkably short, naked. Anterior toes long; the outer scarcely shorter than the middle; the inner shortest; hinder toe very short. Tail long, forked. It is a native of India. (Swainson).

M. longipennis.—Above obscure glossy-green; throat, breast, and lower part of the back, light-gray; belly, spot on the scapulars, and line over the eye, white; ears rufous; front with an incumbent crest.

Mr. Swainson considers *Macropteryx* intermediate between the typical Swifts and the Swallows. To the first, he remarks, it is allied by its strong scansorial feet; to the latter by the length and fixed position of the hind toe, and the depression of the bill.

Head and Foot of *Macropteryx longipennis*.

Chatura, Steph.—Feet as in *Macropteryx*, but the tarsus longer than the middle toe. Tail short, even; the shafts prolonged into acute points. (Sw.)

Long-Winged Swift (*Chatura macroptera*). (Swainson, 'Zoo', Ill., 2nd series.)

C. macroptera is brown, with the wings and tail glossed with greenish-blue, the back being of a gray-white, the chin and under tail-coverts snowy, and the tail even. Mr. Swainson says that *Hirundo albicollis* and it are two of the largest species yet discovered of a very singular group of swifts; wherein the tail-feathers are spined

Tail of *Chatura*. (Swainson.)

and even more rigid than those of the woodpeckers: by this structure, he remarks, the birds can remain for a considerable time in the most perpendicular situations. The expanded tail, he adds, thus acts as a powerful support, which is further increased by the size and strength of the claws, these last being much larger than those of ordinary swallows. Most of the species are natives of America, but Mr. Swainson does not say whether this is a native of that country.

The Wood-Swallows of Australia and India are closely related to the *Hirundinidae*, but differ in the structure of their bills and feet. Mr. G. R. Gray arranges them under his sub-family *Dicruirinae* amongst the *Ampelidae*. They belong to the genus *Artamus*, which is often placed in the *Laniidae*, and is thus defined:—Bill gradually arched from the base, where it is very broad. Culmen thick and convex without any ridge; the base dividing the frontal feathers, and somewhat dilated. Rictus bristled. Nostrils wide apart, naked, small without a membrane, and pierced in the bill. Feet short, strong. Wings very long and pointed; the first quill longest. Tail short. (Swainson.)

A. leucorhynchus is the *Lanius leucorhynchus* of Gmelin, *Pigresische Dominiquaine des Philippines* of Sonnerat, and *White-Bellied Shrike* of Latham. Size rather larger than a sparrow, and in shape much more elongated. Head, neck, breast, back, wings, and tail black. Belly and upper part of the rump white. Under part of the wings (which are very long, and reach at least an inch beyond the tail) gray. Bill grayish, conical, and very strong, slightly curved at its extremity, and its base surrounded with stiff bristles directed forwards. Legs black.

Sonnerat states that this bird flies with rapidity, poisoning itself in the air like the swallows. It is, he adds, an enemy to the crow; and although much smaller, the wood-swallow not only dares to oppose but to provoke him. The combat is long and stubborn, sometimes continuing for half an hour, and concludes with the retreat of the crow. Perhaps, says Sonnerat, the crow despises this too feeble enemy, which only harasses him, and avoids his strokes by his activity, darting away and returning as he sees his opportunity.

A. sordidus, Sordid Thrush, is the *Turdus sordidus* of Latham; *Ocypterus albobittatus* of Cuvier, Valenciennes, and Gould's 'Synopsis'; *Artamus lineatus* of Vieillot; *A. albobittatus* of Vigors and Horsfield; *Leptopteryx albobittata* of Wagler; Be-wö-wen of the aborigines of the lowland and mountain districts of Western Australia; and Worle of the aborigines of King George's Sound.

The head, neck, and the whole of the body, is fuliginous gray; wings dark bluish-black, the external edges of the second, third, and fourth primaries white; tail bluish-black, all the feathers, except the two middle ones, largely tipped with white; irides dark brown; bill blue, with a black tip; feet nearly lead colour. Sexes alike in colour, but the female rather the smallest.

The young have a dirty-white irregular stripe down the centre of each feather on the upper parts, and are mottled with the same on the under parts.

This species is a native of Australia, and breeds from September to December, and the situation of the nest is very much varied. Mr. Gould saw one placed in a thickly-leaved bough near the ground, while others were in a naked fork, on the side of the bole of a tree, in a niche formed by a portion of the bark having been separated from the trunk. He describes the nest as rather shallow, of a rounded form, about five inches in diameter, and composed of fine twigs neatly lined with fibrous roots. He observed that the nests found in Van Diemen's Land were larger, more compact, and more neatly formed than those on the continent of Australia. The eggs, which are generally four in number, differ in the disposition of their markings. The dull white of the ground-colour is spotted and dashed with dark umber-brown; in some Mr. Gould found a second series of grayish spots appearing as if from beneath the surface of the shell. Medium length 11 lines, and breadth 8 lines.

Mr. Gould states that an extraordinary habit of this bird is that of clustering like bees on the dead branch of a tree. "This feature was not seen by me, but by my assistant, Mr. Gilbert, during his residence at Swan River; and I have here given his account in his own words:— 'The greatest peculiarity in the habits of this bird is its manner of suspending itself in perfect clusters, like a swarm of bees; a few birds

suspending themselves on the under side of a dead branch, while others of the flock attach themselves one to the other, in such numbers that they have been observed nearly of the size of a bushel measure.' It was very numerous in the town of Perth until about the middle of April, when I missed it suddenly; nor did I observe it again until near the end of May, when I saw it in countless numbers flying in company with the common swallows and martens over a lake about ten miles north of the town; so numerous in fact were they that they darkened the water as they flew over it."

Sordid Thrush (*Artamus sordidus*). (Gould.)

Mr. Gould gives a representation on the plate which accompanies his description of this extraordinary clustering habit. The birds in the representation at once remind one of a swarm of bees.

Swarm of *Artamus sordidus*. (Gould.)

A. cinereus, the largest of the Australian Wood-Swallows, is the *Ocypterus cinereus* of Valenciennes; and also the Be-wō-weu of the aborigines of the lowland and mountain districts of Western Australia, and the Wood-Swallows of the colonists of the same.

The crown of the head, neck, throat, and chest is gray, passing into sooty gray on the abdomen; space between the bill and the eye, fore part of the cheek, chin, upper and under tail-coverts, jet black; two middle tail-feathers black; the remainder black largely tipped with white, with the exception of the outer feather on each side, in which the black extends on the outer web nearly to the tip; wings deep gray, primaries bluish-gray; under surface of the shoulder white, passing into gray on the under side of the primaries; irides dark blackish-brown; bill light grayish-blue at the base, black at the tip; legs and feet greenish-gray. Sexes alike in colour, and only to be distinguished by dissection. (Gould.)

It is found in Timor and Australia. The range in the last-named country extensive. Found by Mr. Robert Brown at Broad Sound in the east, and by Mr. Gilbert on the west coast.

Wood-Swallow (*Artamus cinereus*). (Gould.)

Mr. Gould states that in Western Australia, although a very local, it is by no means an uncommon species, particularly at Swan River, where it inhabits the limestone hills near the coast, and the Clear Hills of the interior, assembling in small families, and feeding upon the seeds of the *Xanthorhea*, so that insects do not form the sole diet of this species. Mr. Gould indeed observes that with such avidity does it devour the ripe seeds of this grass-tree, that several may be seen crowded together on the perpendicular seed-stalks of the plant busily engaged in extracting them; but he adds that at other times, particularly among the limestone hills, where the trees are few, it descends to the broken rocky ground in search of insects and their larvae.

The round nest is compactly formed in October and November, sometimes of fibrous roots lined with fine hair-like grasses, sometimes with grass-stems and small plants, and placed either in a scrubby bush or among the leaves of *Xanthorhea*. Mr. Gould remarks that it is deeper and more cup-shaped than those of the other members of this group. The eggs vary much in colour and the character of their

markings. Bluish-white is the usual colour, spotted and blotched with lively reddish-brown, intermixed with obscure spots and purplish-gray dashes, the markings most numerous towards the larger end. ('Birds of Australia.')

Nest of Wood-Swallow (*Artamus cinereus*). (Gould.)

SWALLOW-WORTS. [ASCLEPIAS.]

SWANS. [CYGNINÆ.]

SWARTZIA, the name of a genus of Plants, given by Willdenow in honour of Olof Swartz, a Swedish botanist, belongs to the natural order *Leguminosæ*. This order was divided by De Candolle into two groups, *Curcembriæ* and *Rectembriæ*: the former with the radicle of the embryo bent back upon the cotyledons; the latter with the radicle straight. The curcembriose group contains two sub-orders, of one of which, *Swartzia*, the present genus, is the type. The sub-order *Swartzia* is known by possessing a bladder calyx with indistinct lobes, and hypogynous stamens, and by being either destitute of corolla or having only one or two petals. The other genera in this order are *Baphia* and *Zollernia*. [CAMWOOD.] The species are natives of South America and the West India Islands.

The genus *Swartzia* is known by its calyx being divided into 3 or 4 pieces or teeth, which are at first united, but afterwards break up and separate. It has sometimes one petal, which is flat and lateral; sometimes this is entirely wanting. The stamens are 10, 15, or 25 in number, with frequently 2 or 4 of them much larger than the others, and the rest are often connected a little way at the base. The seeds have an arillus, and do not possess albumen. The species are trees, with simple or unequally pinnated leaves, having racemose flowers, which grow from the axils of the leaves.

S. tomentosa, Tomentose Swartzia. Leaves with 5-7 leaflets; petioles terete, which, as well as the branchlets, are velvety; leaflets oval-oblong, pointed, velvety beneath; stipules nearly orbicular. This species forms a high thick tree, with strong angular branches, and grows on the borders of rivers in Guyana, where it is called Anacoco and Bois Pagaie Blanc. It has a fine reddish-coloured wood, which becomes black by age, and is considered very indestructible, and is used for the making of rudders for ships. The bark is very bitter, and is used as a medicine in its native country. There are about 16 other species of *Swartzia*.

SWEAT. [SKIN.]

SWEET BRIAR. [ROSA.]

SWEET CALAMUS. This aromatic, which was of equal celebrity with Spikenard, mentioned by the same authors, and procured from the same country, is described by Dioscorides under the name of *Kάλαμος ἀρωματικός*. It is supposed by Sprengel and some authors that the *Acorus Calamus* of botanists is intended, which is possessed of slight aromatic properties, is common in European ditches, and is likewise found in India in mountainous situations. This is known to the Arabs by the name Wuj, which appears to be a corruption of the Hindoo Bueh, Sanscrit Vacha, and has in the Arabian works the name Akoron assigned as its Greek synonyme, no doubt intended for the *Akoron* of Dioscorides. Therefore there is no foundation for the opinion of Sprengel that this Acoron is the *Iris pseudacorus* of botanists.

Calamus aromaticus is described by Dioscorides immediately after *Σχοῖνος*, or *Σχίμος*, which is usually translated *Juncus odoratus*, and is acknowledged to be the *Andropogon Schenanthus* of botanists, commonly known by the name of Lemon-Grass. This has also had the names of Camel's Hay, Pulca de Mecha, &c., applied to it. *Schenanthus*

is evidently compounded of 'schoenus' and 'antbos' (*άνθος*, 'a flower'). Theophrastus treats of Calamus and Schoenus together, and states that they were found among the mountains of Lihanus, on the shores of an extensive lake; but Burckhardt in such situations could only find rushes and reeds. It is possible therefore that a Syrian locality may have been assigned to drugs obtained from more distant countries by the route of the Euphrates, for Dioscorides says they are produced in India. By Hippocrates they are called *Kάλαμος εὐώδης* and *Σχοῖνος εὐώδης*, also *Kάλαμος σχοῖνος* (Hipp., f. 5 p. 138, l. 17), evidently showing that if they agreed in properties, they had also some resemblance in nature. If we desire to find something similar to *Schenanthus*, and possessed of still more aromatic properties, we have only to search in the genus to which this belongs, and we shall find several plants famous for their agreeable odour. The roots of *Andropogon muricatum*, commonly known in the shops of this country by the Tamul name Vitivayr, and made into small bundles for brushing velvet, are remarkable for their fragrance: hence several essences are now prepared from them in Paris. The roots are also well known to Indians by the name of Khuskhus, being used throughout the Bengal Presidency for making tattees; these thatched screens being fitted to doors and windows, have water constantly sprinkled over them; the hot air in passing through becomes much cooled by the great evaporation, and enters the room hot and refreshing, diffusing a delightful fragrance. The aroma here depends on the presence of a principle analogous to myrrh. But other species are still more fragrant, and secrete odorous volatile oil in sufficiently large quantities to be profitably distilled. Of these, Lemon-Grass, or *Andropogon Schenanthus*, is the best known. The infusion of its leaves is often employed in India as a pleasant stomachic, and Lemon-Grass Oil is probably distilled from them. *A. Nardus* (?) is another species, called Ginger- or Spice-Grass, by Ainslie, which is said by him to be common in the Courtallum Hills and the Indian Peninsula, where the natives occasionally prepare with it an essential oil useful in rheumatism, and use the infusion of its leaves as a stomachic. *A. Iwarancusha* is a species which comes near *A. Schenanthus* in habit and taste. It skirts the bases of the mountains of north-west India, and was found by Dr. Blane and by Dr. Boyd about Hurdwar: it was considered by the former to be the Spikenard of the ancients. Dr. Royle also found it near Hurdwar, and in the upper parts of the Doab of the Ganges and Jumna rivers, and he states ('Illustr. Himal. Bot.,' p. 425) that it is there called Mirchiagund, with Izkbir given as its Arabic, and Iskhinos as its Greek synonym; and infers that it may have been the *Σχοῖνος* of the Greeks as well as *A. Schenanthus*. But another species is still more extensively diffused, and still more remarkable for its very powerful and delightful fragrance. This is the species which yields the Grass-Oil of central India, commonly called Oil of Spikenard. It extends southward to between the Godavery and Nagpore, and northward to the Delhi-territory, but probably still farther north, as it delights in a dry and barren soil. In central India, especially at Namur, Ellichpore, &c., a very delightful fragrant oil is distilled from this plant, which is highly valued in the East as a scent, being added to the finer expressed oils employed for anointing the hair or the bodies of the natives. It is also much esteemed as an external application in rheumatism, and has been introduced into practice in this country, and is highly valued by some, though unknown to the generality of practitioners. It has the advantage of diffusing an agreeable odour at the same time that it is efficacious as a stimulant remedy. This or the preceding species extends into Afghanistan.

Sweet Cane, or Calamus, being described by Dioscorides immediately after *Σχοῖνος*, which is generally acknowledged to be *A. Schenanthus*, appears to Dr. Royle to belong to the same genus, and indeed to be the above far-famed species, as *Calamus aromaticus* is thought also to be the Sweet-Cane and the rich aromatic reed from 'a far country' of Scripture. He states that there is no plant which more closely coincides in description with everything that is required than the tall grass which yields the fragrant Grass-Oil of central India, and which he has named *A. C. aromaticus*. ('Illustr. Himal. Botany,' p. 425.)

SWEET GUM-TREE. [LIQUIDAMBAR.]

SWEET-SOP. [ANONACEÆ.]

SWEET-WILLIAM. [DIANTHUS.]

SWIETENIA, a small genus of Plants of the natural family *Cedrelaceæ*, named by Jacquin in honour of G. van Swieten. The genus *Swietenia* is characterised by having a small 4-5-cleft calyx; petals 4 to 5, deciduous; stamens 8 to 10, the filaments united together into a toothed tube, bearing the anthers on the inside; stigma peltate; ovary 6-celled, seated on a stipes; seeds winged. The species, though few in number, are found in hot parts of the world, form large trees, and yield valuable timber.

S. febrifuga of Roxburgh has been formed into a new genus, *Soymidia*. [SOYMIDA.]

S. Senegalensis has also been formed into a new genus, *Khaya*, and is the tree yielding African mahogany, which is brought to us from Sierra-Leone. The timber, though hard, is liable to warp, but it is employed where a hard and cheap wood of large size is required, as for mangles. The negroes employ an infusion of the bark, which is very bitter, as a febrifuge.

S. chloroxylon is a third species, which has been formed into a new genus, and is now *Chloroxylon Swietenia*, a native of the mountainous

parts of the Circars in the East Indies. It is the tree yielding the beautiful East Indian satin-wood, which is of a deep yellow-colour, close-grained, heavy, and durable.

S. Chikrassee, now *Chikrassia tabularis*, is a fourth species, formed into a new genus. This is another Indian tree which is greatly admired for its beauty. The wood is very light-coloured, close-grained, and most elegantly veined, and much employed for furniture and cabinet-work.

The most important species, however, and that which now nearly alone constitutes the genus, is *S. mahogany*, a native of Campeachy and of the West Indies. It is a lofty branching tree with a large spreading head, and pinnate shining leaves. The timber, which is so well known from its extensive employment for furniture and cabinet-making, is of a reddish or yellowish-brown colour, of different degrees of brightness, much mottled and streaked, very little liable to shrink or warp, free from taste or smell, except when kept for some time, when it acquires an agreeable odour, from the exudation of a semi-resinous juice, which serves to preserve the wood from the attacks of insects. It does not appear to have been imported into this country before 1724. The quality of the wood varies much, according to the situations in which it grows: that which is produced on rocky soil and exposed situations is the best. Spanish mahogany is imported in logs of about 10 feet long, and from 20 to 26 inches square. From the elevated parts of the West Indies and from the Spanish Main the wood is close-grained, and of a darker colour than the Honduras mahogany. This is imported in logs of from 2 to 4 feet square, though both kinds are no doubt produced by the same tree. Some years ago the Messrs. Broadwood gave the large sum of 3000*l.* for three logs of mahogany, which were each about 15 feet long and 38 inches square. The wood was extremely beautiful, and capable of taking the highest polish.

SWIFT. [SWALLOW-TRIBE.]

SWIMMING. A large number of animals transmit themselves from place to place by swimming in liquids; and when we take a view of the variety of forms presented by the locomotive organs of these animals, it must be apparent that they perform their movements very differently. All those land animals which constantly breathe the air, especially man and the higher orders, must float on the surface of the water in swimming; they die of suffocation when water chokes up the air-tubes of the lungs, which constitutes drowning. Of all animals, there is perhaps none so helpless in water, without training, as man; and notwithstanding his vast superiority in other respects to other air-breathing animals, he is inferior to them in the employment of the locomotive organs for the purposes of swimming. Indeed it is well known that by far the greater number of persons who are precipitated into deep water, if they cannot swim, are drowned. This arises from the improper use they make of their limbs.

The cause of this misapplication of the limbs by man, when immersed in water, is owing to the totally different mode in which they are used in walking and running on land to that in which they should be exercised in water, as we shall see.

In preparing to swim, in man, the limbs should be arranged in such a manner that they can be made to act favourably as soon as the body is resting, unsupported by other media, in the water.

In order to propel the body there must be some movement of the limbs; and it is by the flexion and abduction of the arms, and by the extension and adduction of the legs, that the process of swimming is performed, which movements must be produced rhythmically. Suppose a person standing up to his breast in water and about to strike off in swimming; the hands are placed close to each other with the palms undermost near the breast, the body is thrown forward in the water, the hands are thrust out, and when the arms are fully extended as in *fig. 1*, they diverge horizontally (the backs of the hands being

Fig. 1.

Fig. 2.

turned towards each other), describing curves until they are brought round under the armpits, and again extended. It should be observed

that the arms must always be kept in advance of a line passing through the axes of the shoulder-joints.

Let us now advert to the action of the legs. Whilst the arms are describing their curves the legs are drawn forwards under the body, the knees being separated as much as possible, and the toes turned outwards as in *fig. 3*, and whilst the arms are regaining their extended

Fig. 3.

position the legs are extended backwards and outwards with a moderate degree of velocity, the soles of the feet being turned outwards, and are then brought together again, simultaneously with the arms, into the attitude shown in *fig. 1*.*

It will be observed that the arms and legs have each four distinct kinds of motion, namely, extension, abduction, adduction, and flexion, but the effects of these motions are different. The extension of the arms retards the motion of the body, whilst that of the legs accelerates it: the abduction of the arms accelerates, and of the legs slightly retards; the adduction of the arms slightly retards, and of the legs accelerates; and the flexion of both arms and legs retards. The simultaneous performance of these motions is exhibited in the following tabular form:—

Arms.	Legs.
Abduction	Flexion
Adduction }	{ Extension
Flexion	{ Abduction
Extension	Adduction

It is upon the rhythm with which these periodic movements are performed that the success of swimming depends, the whole being seen in outline in *figs. 1 and 3*.

We may also observe, that when the arms are abducted, or drawn outwards and backwards, the legs are drawn forwards; and when the arms are flexed and brought together, the legs are extended outwards; and lastly, when the arms are thrust forwards, the legs are brought close together; so that whilst the force of the arms is positive, that of the legs is negative, and vice versa: but it is evident that the effective forces in swimming preponderate, or the body would either remain stationary or move backwards, and this results from the shape of the limbs and the manner in which they can be made to act.

From what has been said, we may easily perceive how differently the limbs act in swimming from what they do in walking, and that the arms and legs interchange their effective strokes alternately. These movements are not difficult to perform, but it requires some attention and practice in order to accomplish them with precision. Indeed they may be practised out of water, and sufficient habit be obtained to know how to act if by chance a person were suddenly immersed and in danger of being drowned. But it should also never be forgotten that almost all persons will float, if the chest be kept well filled whilst immersed in the water. It however requires great fortitude and self-possession to keep the limbs quiet and under water, and at the same time to stop the inspiratory movement until the mouth rises above the surface of the water.

Swimming on the back is usually effected by means of the legs alone. The attitude preparatory to this movement is seen in *fig. 4*.

Fig. 4.

The head is bent backwards so far that the water may cover the forehead, and reach to the level of the eyes; the chest is elevated, and the hands placed on the hips; the motions of the legs are indicated by the dotted lines in *fig. 2*, and are the same as those of the legs in swimming on the breast. We may here state that any one who can swim on his breast will experience no more difficulty in

* These figures are reduced from the 'Elementary Course of Gymnastic Exercises' by Captain Clias.

turning himself round on his back in the water than in turning himself in his head.

Some persons can accomplish swimming on the side, and others on the back, without using the legs; and many other feats, such as with the arms acting in different directions as seen in *fig. 5*, and again

Fig. 5.

with one hand alone. In diving, two methods are recommended: one by leaping into the water with the feet downwards, the other head foremost; the former is most desirable in shallow water, the latter when the head is subject to giddiness and fullness of blood.

Figs. 6 and 7 show the attitude preparatory to plunging into the water, and *fig. 8* the position of the limbs in diving to the bottom of the river.

Figs. 6, 7, and 8.

The position of greatest ease in the water is floating. The body lies on the back, with the face only above the water; the limbs are perfectly quiescent, and extended as in *fig. 9*. This state can only be maintained when the specific gravity of the body is less than that of the water.

Fig. 9.

Sea-water, being heavier than that of rivers, is best calculated to support a person in swimming, and those who are specifically heavier than river-water may be sustained in a floating position in sea-water. It may be observed that man being so nearly of the same specific gravity as water, and air being nearly 1000 times lighter, that a few cubic inches of air in a bag are sufficient to keep one who cannot swim permanently at its surface; or a few pounds of cork fastened to the body will accomplish the same object: and it is astonishing that, notwithstanding the great number of persons who are annually drowned in the Thames alone, no means are adopted to provide some such simple method for sustaining the body in water by boatmen; and still more that we hear of watermen being frequently drowned in consequence of not having learned to swim. Swimming ought to form a part of our physical education; all our youth of both sexes may do so with advantage, for the purpose of cleanliness and to increase their health and strength, as well as to provide a safeguard against subsequent accidents.

The specific gravity of nearly all Mammiferous Quadrupeds is less than that of water, and hence they are capable of floating on its surface without requiring the interposition of the limbs. We have familiar examples of the specific gravity of quadrupeds in the horse,

dog, cat, deer, &c. If, for instance, we cause either of the above-named animals to be thrown into deep water, we observe that they speedily rise to the surface, and remain there as long as the limbs are quiescent, and when the limbs move they strike out in the proper direction with precision, although they may never previously have been out of their depth in water. But if we inquire how it happens that these animals are enabled, without the aid of experience, to swim at once the first time they are plunged into water, we find on investigation that the limbs of Mammiferous Quadrupeds move in water precisely as they do on land, and no new action, either as regards direction or order, is required, as is the case with man, to enable them to swim; and as they are specifically lighter than water, they need no force to be employed to keep them above the surface. In hunting the stag or the fox, it is not an uncommon occurrence for the animal, when hard pressed in the chase, to plunge into a stream and swim across the water, the hounds following. The huntsman, relying on the tact of his horse, plunges fearlessly with it into the water, and arrives safely on the opposite bank. In these cases the horse carries its rider above the surface, thus showing that the specific gravities of the man and horse combined are much less than that of the water.

Most of the Mammiferous Animals are amphibious, and possess the faculty of sustaining themselves during lengthened periods under water. Of these, several species have the feet furnished with a membrane between the fingers and toes; such, for example, as the Otter tribe. These animals are excellent swimmers, and their agility in the water is surprisingly great. It appears that nearly all mammiferous animals can swim if necessitated to do so; and it should be borne in mind that this has been accounted for by their being gifted with two qualities essential in swimming—the one arising from specific gravity, and the other from the circumstance of the natural movements of the limbs being the same both on land and in water.

Amongst the Birds, those of the order *Natatores* are, as their generic name implies, best adapted for swimming. The figure of the breast resembles that of the keel of a boat; the body being clothed with a thick plumage, tends to increase the bulk without very materially augmenting the weight. The plumage is very compact, and being lubricated with an oleaginous secretion, the water cannot penetrate to the skin. The bones of the skeleton are extremely light, and many of them are hollow, so that the specific gravity of birds is much less than that of water; indeed, were it not so, they would be utterly unable to swim, and much less to fly in the rarer medium of air. The specific gravity of birds is so much less than that of water, that we observe, as in the Grebe, Petrel, &c. (*fig. 10*), that by far the greater

Fig. 10.

Grebe Petrel.

portion of the body is above the water as they lie flat on its surface. They require therefore no action of the limbs to sustain them on the

Fig. 11.

Foot of Grebe.

water, and, for the purpose of progression, the feet, which act as oars, are variously and most exquisitely contrived. For example, in the Grebe each toe is furnished with a distinct membrane (*fig. 11*), the margins of which overlap each other; but in the Merganser, and many other aquatic birds, such as the Duck and Goose, the same membrane extends to the three toes. (*Fig. 12*) In swimming, the

Fig. 12.

Elder Duck.

effective stroke is produced by the feet alternately; that is, whilst one foot is pushed backwards the other is drawn forwards. (*Fig. 13*.)

Fig. 13.

Parakeet Auk.

In the effective stroke the foot is extended and the toes expanded so as to present the greatest surface possible to the water; it is then driven backwards with force, the effect of which is to drive the body forwards. In the back stroke the foot is flexed, and the toes are brought together so as to present the least surface to the water, and produce as little action as possible. The back stroke of the leg tends to retard the body, and it is only the difference in the amount of the force of these strokes that is effective. Sometimes both feet are driven backwards and drawn forwards simultaneously, and the body moves by a series of jerks.

Some of the water-birds make use of their wings as sails; the swan, for instance, may be often observed partially to elevate the wings and spread them out to the wind, and thus move by the force of the wind alone, like a sailing vessel.

It is well known that Fishes reside constantly in water; they are indeed so organised that they can neither live nor move out of it but for a very short time. Their specific gravity is very nearly equal to that of water; but they are also endowed with the power of varying their specific gravity, so as to raise or lower themselves in the fluid at pleasure. We have seen that the human race can vary the specific gravity of the body, by drawing in and expelling the air from the lungs; but fishes, not having the same kind of respiratory organs, cannot do so in the mere act of respiration. As a large number of fishes however are obliged to sustain themselves surrounded on all sides by the water, it would require an endless play of muscular force to retain them in such a position, if their specific gravity were either greater or less than that of the water. To prevent this continual waste of vital power, they have been provided with an air-bladder,

which they have the power of distending and contracting at pleasure: this bladder is placed in the body immediately under the spine, and above the centre of gravity, being the best position to keep the body steady, and prevent its turning over when the air-bladder is distended. When the air-vessel is filled the animal is lighter than water, and it rises; and when the air is expelled it becomes heavier, and sinks. This hydrostatic apparatus cannot but strike with admiration every one who contemplates the beautiful adaptation of fishes to the end they are destined to serve in animal creation.

Some fishes, such as the rays and soles, are destitute of a swimming-bladder; but as they generally reside at the bottom of the sea, they do not require one: when they swim, in order to prevent their sinking, they must use as much extra force as is conferred on other fishes by the air-bladder. The locomotive organs of fishes consist of fins and tail, the former of which are variable in size, number, and direction. The figures of fishes are also various, but in some of them, such as the cod, salmon, and mackerel, the figure is supposed to approximate, more nearly than others, to that which is considered by mathematicians to offer the least resistance to their progress in the dense medium they inhabit. In the perch tribe we find the greatest number of fins, being as many as eight; these are termed the two pectoral, two dorsal, two ventral, one anal, and one caudal. These several names are given in consequence of their relative situations on the body. The pectoral fins are supposed to represent the arms, and the anal fins the legs, of the higher orders of animals. In the gurnard it may be remarked that the pectoral fins (*fig. 14, a, a'*) are very large, as

Fig. 14.

Gurnard.

are also the dorsal (*b c*); the caudal (*c*) increases in surface as it recedes from the body. The whole of the fins are more or less employed in certain kinds of movements.

Fig. 15.

c b, parallel to *o e*. If the two forces *c h* and *c b* acted simultaneously, we should obtain the resultant *c f*; but as they do not, the point (*c*) will not move exactly in the right line *c f*, but in a curved

In order to ascertain the true use of the fins in swimming, Borrelli having cut off the ventral fins of a living fish, put it back again into the pond. It then rolled from side to side like a drunken man, and could not keep an upright position. When the fish move with great velocity the pectoral fins are laid close to the body, in order that they may not retard its motion; and in rapid motion the tail becomes the great propelling organ of motion. We shall therefore now investigate its mode of action. The first movement of a fish from a state of rest is produced by the flexion of the tail (as seen in *fig. 15*, at *a*); during this movement the centre of gravity (*c*) is drawn slightly backwards. When the tail has arrived at *a*, it is forcibly extended by its muscles in the direction *a i*, perpendicular to its plane: the force of its action upon the water, in *a i*, is translated to the fish in the direction of *i a*, causing the centre of gravity (*c*) to move obliquely forwards, in the direction *c h*, parallel to *i a*. The tail having reached the central line *c d*, its power of urging the body forwards not only ceases, but during its flexion on the opposite side in the line *a o*, it tends to draw the body backwards, in the direction *o c*. Having reached the point *o*, it is again rapidly extended in the line *o e*, causing an impulse on the centre of gravity in

line which lies evenly between *d e f* and a line drawn parallel to it through *h*. The fish being in motion whilst the tail moves from side to side, according to Borrelli, it describes an ellipse instead of a circular arc, which would be the case if the body were stationary and the tail only moving. The velocity with which fishes move, and the continuance of their movements, are enough to give us an idea of the great strength of their muscles, especially when we reflect on the density of the fluid which is opposed to their speed. Those fishes which have occasion for great speed (such as the shark, as well as other predaceous fishes), have their tails forked (Fig. 16). In these the area of the surface

Fig. 16.

Tail of Shark.

of the tail is in the inverse ratio of the distance from its axis of motion. This figure is that which may be considered best adapted for great velocity of progression. When the surface of the tail increases as its distance from the centre of gravity of the animal, the muscles act at a mechanical disadvantage, and the animal can proceed but slowly. In whales the surface of the tail is proportional to the enormous bulk of the body; but the plane of the tail is transverse, or in the mesial plane of the body, instead of being perpendicular as in fishes; and its action is at right angles to that of fishes also. The force of the tail must be very great, inasmuch as they have been observed to throw themselves quite out of the water, many feet in height, into the air.

As we descend lower in the scale of organised beings, we find an illimitable number of aquatic animals. The lobster, prawn, and shrimp, swim backwards by the action of the tail; but in these the effective stroke is during the flexion of the tail, and not the extension, as in fishes. Many insects are also aquatic, such as the *Dytiscus* and others. [FLYING; LOCOMOTION IN ANIMALS.*]

SYLVIA. [ERTHACA; SYLYIADÆ.]

SYLVIADE (Vigors), a family of Birds belonging to the tribe *Dentirostres* and the order *Insectores*.

Mr. Vigors remarks that the *Sylviadæ*, the Warblers of our British ornithologists, assimilated as they are to the *Merulidæ* in the sweetness and compass of their vocal power, are separated from that family chiefly by their more delicate structure and more subulate bill. That portion of the Linnæan *Motacilla*, or rather of the *Sylvia* of Latham, he observes, which Bechstein has separated from the genus under the title of *Accentor*, in conjunction with that which embraces the Nightingale (*Sylvia luscinia*), appears to be the group most nearly approaching the Thrushes by the comparative strength of its formation. Here also, perhaps, he thinks we may find the *Hylophilus* (Temm.) of the New World, and the *Iora* (Horsf.) of the East, to be united by their stronger bills. Hence, he continues, a number of intervening groups (among which *Brachypteryx*, and that which includes *Sylvia rubecola*, the Red-breast, are specially noticed by him) conduct the inquirer by their gradually lessening bill and more slender form to those birds in which the delicate body, the tapering legs, and the gracile and subulate bill point out their typical supremacy in the family. To these latter groups he considers *Melizophilus* (Leach), the Dartford Warbler, and *Malurus* (Vieill.), the representative of *Sylvia* in Australasia (in both of which the bill deviates from that of the conterminous genera in the culmen being somewhat arched), nearly allied, and also the Wrens (*Troglodytes* and *Regulus*, Cuv.). To these he makes succeed a number of groups whose lengthened tarsi indicate that their natural station is on the ground, such as *Budytes* (Cuv.), the true *Motacilla* of authors; and *Enicurus* (Temm.); and here he would add *Megalurus* (Horsf.) and *Anthus* (Bechst.), which unite, in his opinion, the *Dentirostres* with the *Coniostres*, by means of the Larks (*Alauda* of authors). Mr. Vigors then states that *Saxicola* (Bechst.) is nearly allied to the Larks in its terrestrial habits and general conformation; but which, by its increasing bill, brings us round to the earlier groups of the present family, and thence to the *Merulidæ*, with the section of which it is, he thinks, nearly connected. The circular disposition by which the extremes of different families may be brought into contact with each other, explains, in his view of the case, the manner in which the genus *Saxicola*, the

section of *Merles Saxicoles*, the genus *Myiothera*, and the more delicate forms of *Thamnophilus*, all birds decidedly approaching each other, yet belonging to the different families of *Sylviadæ*, *Merulidæ*, and *Laniadæ*, still preserve their union, and are brought together into a conterminous assemblage.

The True Wrens display, in his opinion, so close a similarity in their general appearance and habits to *Parus* (Linn.), the Titmouse, that we may at once acknowledge the affinity between the latter family and the *Pipridæ*, upon which family he enters by the Titmice. ('Linn. Trans.,' vol. xiv.)

Mr. Swainson thus arranges this family, "marked by peculiarities of habit no less than by a variation of structure applied to such habits:"—

Circles.	<i>Sylviadæ</i> , or Warblers.	Sub-Families.
1. Typical . . .	{ Bill very slender, compressed; lateral toes equal	{ <i>Sylvianæ</i> .
2. Subtypical . . .	{ Bill and general structure more robust	{ <i>Philomelinæ</i> .
	{ Bill depressed at its base; legs lengthened; strong	{ <i>Saxicolinæ</i> .
3. Aberrant . . .	{ Claws lengthened, and but slightly curved; live upon the ground	{ <i>Motacillinæ</i> .
	{ Bill strong, almost entire; hinder toe and claw large	{ <i>Parianæ</i> .

Of this group the *Motacillinæ*, in Mr. Swainson's opinion, form the most aberrant division. Purely insectivorous, they are, he remarks, well exemplified by the four common and well-known species distributed through this country and Europe generally. "They live," says Mr. Swainson, "almost entirely upon the ground, where alone they seek their food, which consists entirely of insects: damp meadows, and the sides of standing or running waters, are the favourite haunts of these birds; and they run with such celerity, that, in this respect, as well as in their general black and white plumage, they can only be compared to the plovers." He considers them, in fact, as collectively representing the tenuirostral type of the perchers; or, what is the same, the gallatorial type among birds.

Mr. Swainson enters among the *Parianæ*, or Tits, by the American genus *Seiurus*; and among the True Warblers (*Sylvianæ*) by the genus *Culicivora*, comprising the Gnat-Snappers.

The union of all these sub-families is, in Mr. Swainson's view of the case, effected by the *Gryllivora*, a genus of *Saxicolinæ* uniting to *Enicurus*, which stands at the confines of the Wagtails (*Motacillinæ*).

The following genera are comprised under this family, according to Mr. Swainson's arrangement:—

Sylviadæ.—Size universally small. Bill very slender, distinctly notched. Feet formed for walking, perching, or climbing. Tarsus slender, lengthened. (Sw.)

Saxicolinæ, Stouechata.—Bill depressed at the base: gape with diverging bristles. Feet lengthened. Tail rather short. Head large.

Genera:—*Gryllivora*, Sw.; *Thamnobia*, Sw.; *Saxicola*, Bechst.; *Erythaca*, Bechst. (Robins) (with the sub-genera *Erythaca*, Sw., and *Sialia*, Sw.); *Petroica*, Sw.

Philomelinæ, Nightingales.—General structure larger and more robust than the typical warblers. Feet formed for perching.

Genera:—*Phenicura*, Sw. (Redstarts); *Philomela*, Antiqu. (Nightingales); *Currucula*, Bechst.; *Bradypterus*, Sw.; *Agrobates*, Sw.

Sylvianæ, True Warblers.—Size very small. Structure weak. Bill very slender, straight, and with the under mandible much thinner than the upper. (Sw.)

Genera:—*Orthotomus*, Horsf.; *Malurus*, Vieill. (with the sub-genera *Hemipteryx*, Sw.; *Drymoica*, Sw.; *Melizophilus*, Leach; *Malurus*, Vieill.); *Sylvia*, Lath (with the sub-genera *Sylvia*, *Acanthiza*, Horsf. and Vigors; *Regulus*, Ray; and *Cyanotis*, Sw.); *Culicivora*, Sw.; *Praticola*, Sw.

Parianæ, Titmice.—Bill either entire or very slightly notched, more or less conic. Tarsus never shorter than the hind toe, which is large and strong. Lateral toes unequal. (Sw.)

Genera:—*Setophaga*, Sw.; *Sylvicola*, Sw. (with the sub-genera *Dumecola*, Sw.; *Sylvicola*, Sw.; *Vermivora*, Sw.; *Mniotilta*, Vieill.; *Zosterops*, Horsf. and Vigors); *Parus*, Linn. (with the sub-genera *Agithina*, Vieill.; *Agithalus*, Vig.; *Parus*, Linn.; *Parusoma*, Sw.; and *Hylophilus*, Temm.); *Accentor*, Bechst. (with the sub-genus *Seiurus*, Sw.); *Trichas*, Sw.

Motacillinæ, Wagtails.—Bill lengthened; very straight and slender. Legs long, formed for walking. The hind toe much longer than the rest. Wings pointed. Tail narrow, and much lengthened. (Sw.)

Genera:—*Lessonia*, Sw.; *Budytes*, Cuv.; *Motacilla*, Linn.; *Enicurus*, Temm.; *Anthus*, Bechst.

The family stands between the *Merulidæ* and the *Ampelidæ*. ('Classification of Birds.')

The *Calamoherpina*, *Sylvina*, *Saxicolinæ*, *Motacillinæ*, *Parianæ*, and *Sylvicolinæ*, are arranged by Prince Bonaparte under his family of *Turdidæ*. [MERULIDÆ.]

Mr. G. R. Gray makes the *Sylviadæ* the first family of his third tribe (*Dentirostres*) of *Insectores*, with the following sub-families:—

1. *Malurinæ*.

Genera:—*Orthotomus*, Horsf. (*Edela*, Less.); *Prinia*, Horsf.; *Drymoica*, Sw. (*Sylvia*, Lath.); *Cyanotis*, Sw. (*Sylvia*, Vieill., *Tachuris*

* This article forms the concluding part of LOCOMOTION IN ANIMALS, for which we are indebted to Mr. J. Bishop.

D'Orb.); *Regulus*, Gray; *Bradypterus*, Sw. (*Sylvia*, Vieill., *Cysticola*, Less.); *Apalis*, Sw.; *Praticola*, Sw. (*Calamanthus*, Gould, *Anthus*, Vig. and Horsf.); *Cysticola*, Less. (*Salicaria* (?) Gould, *Sylvia*, Temm.); *Melospiza*, Leach (*Motacilla*, Gm.); *Hemipteryx*, Sw. (*Sylvia*, Vieill., *Cysticola*, Less.); *Stipiturus*, Less. (*Drymoica*, Sw., *Sylvia*, Lath., *Malurus*, Temm.); *Malurus*, Vieill. (*Motacilla*, Gm.); *Cinchoramphus* Gould (*Megalurus*, Vig. and Horsf.); *Sphenura*, Licht. (*Turdus*, Lath., *Malurus*, Temm.); *Megalurus*, Horsf. (*Malurus*, Reinw.); *Yuhina*, Hodg. With reference to *Yuhina*, Mr. Gray remarks that it is the same perhaps as the preceding genus.

2. Sylviina.

Genera:—*Cettia*, Bonap. (*Sylvia*, Marm., *Salicaria* (?) Gould); *Pseudo-Luscinia*, Bonap. (*Sylvia*, Savi); *Locustella*, Ray (*Sylvia*, Lath., *Salicaria*, Selby, *Calamohérpe*, Brehm, *Curruca*, Sw., *Arundinaceus*, Less.); *Calamodytes*, Bonap. (*Sylvia*, Temm., *Arundinaceus*, Less.); *Acrocephalus*, Naum. (*Calamohérpe*, Boie, *Motacilla*, Linn., *Salicaria*, Selby, *Curruca*, Sw., *Arundinaceus*, Less.); *Hippolais*, Brehm (*Asilus*, Bechst., *Arundinaceus*, Less., *Motacilla*, Linn.); *Regulus*, Ray (*Motacilla*, Linn.); *Phylloscopus*, Meyer (*Sylvia*, Lath., *Phylloscopus*, Boie, *Asilus*, Briss., *Trochilus*, Lafr.); *Sylvia*, Lath. (*Philomela*, Sw.); *Curruca*, Briss. (*Motacilla*, Gm., *Sylvia*, Lath.); *Nisoria*, Bonap. (*Curruca*, Brehm, *Philomela*, Sw.); *Luscinia*, Briss. (*Philomela*, Sw., *Daulias*, Boie, *Motacilla*, Gm., *Sylvia*, Lath.).

3. Saxicolina.

Genera:—*Copsychus*, Wagl. (*Gracula*, Gm., *Gryllivora*, Sw., *Cercotrichas*, Boie, *Lalage* (Boie), Snudov., *Kittacincta*, Gould, *Notodola*, Less.); *Ruticilla*, Ray (*Picedula*, Bechst., *Phenicura*, Sw., *Motacilla*, Linn.); *Cyanocitta*, Briss. (*Pandicilla*, Bl., *Motacilla*, Linn., *Sylvia*, Lath.); *Calliope*, Gould (*Accentor*, Temm., *Motacilla*, Linn., *Turdus*, Gm.); *Orocetes*, G. R. Gray (*Phenicura*, Vig., *Petrophila*, Sw.); *Rubecula*, Briss. (*Dandalus*, Boie, *Erythaca*, Sw., *Motacilla*, Linn.); *Sialia*, Sw. (*Sylvia*, Lath.); *Petroica*, Sw. (*Muscicapa*, Gm.); *Origma*, Gould (*Muscicapa*, Lewin., *Saxicola*, Vig. and Horsf.); *Edon*, Boie (*Erythropygia*, Smith, *Arundinaceus*, Less., *Salicaria*, Gould, *Agrobates*, Sw.); *Thamnobia*, Sw. (*Sylvia*), *Besonornis*, Smith; *Campicola*, Sw. (*Sylvia*, Lath., *Saxicola*, Temm.); *Vitisora*, Briss. (*Enanthe*, Vieill., *Saxicola*, Bechst., *Motacilla*, Linn.); *Rubetra*, Briss. (*Motacilla*, Linn., *Saxicola*, Bechst.).

4. Accentorina.

Genera:—*Accentor*, Bechst., (*Motacilla*, Gm.); *Enicocichla*, G. R. Gray (*Seiurus*, Sw. (*Turdus*, Will.); *Trichus*, Sw., (*Turdus*, Linn.); *Sericornis*, Gould (*Acanthiza*, Vig. and Horsf.); *Acanthiza*, Vig. and Horsf.; *Ptilopus*, Gould; *Symmorphus*, Gould; *Iora*, Horsf. (*Motacilla*, Linn.).

5. Parina.

Genera:—*Agithalus*, Vig. (*Remiz*, Cuv., *Pendulinus*, Brehm, *Parus*, Linn.); *Melanochlora*, Less. (*Parus*, Lafr.); *Parus*, Linn.; *Suthora*, Hodg.; *Minla*, Hodg.; *Mesia*, Hodg.; *Bahila*, Hodg.; *Siva*, Hodg.; *Megistina*, Vieill. (*Parus*, Gm.); *Tyrannulus*, Vieill. (*Pipra*, Spix., *Sylvia*, Lath.); *Sphenostoma*, Gould; *Calamophilus*, Leach (*Mystacinus*, Boie, *Parus*, Linn.); *Megistura*, Leach (*Orites*, Mohr, *Paroidea*, Brehm, *Parus*, Linn.); *Parisoma*, Sw. (*Sylvia*, Vieill.); *Psaltia*, Temm.; *Agithina*, Vieill.; *Hylophilus*, Temm.

6. Sylvicolina.

Genera:—*Sylviparus*, Burt; *Dumecola*, Sw.; *Sylvicola*, Sw. (*Parus*, Linn., *Sylvia*, Lath., *Chloris*, Boie, *Parula*, Bonap.); —? (*Wilsonia*, Bonap., *Muscicapa*, Wils., *Scotaphaga*, Sw.); *Vermivora*, Sw. (*Picedula*, Briss., *Sylvia*, Lath.); *Mniotilta*, Vieill. (*Oryzopsis*, Sw., *Sylvia*, Lath., *Sylvicola*, Jardine); *Zosterops*, Vig. and Horsf. (*Sylvia*, Sw.).

7. Motacillina. Motacilla, Linn.

Genera:—*Muscisaxicola*, D'Orb. (*Lessonia*, Sw., *Ptionura*, Gould); *Motacilla*, Linn.; *Budytes*, Cuv. (*Motacilla*, Linn.); *Enicurus*, Temm. (*Motacilla*, Linn.; *Turdus*, Vieill.); *Grallina*, Vieill. (*Tanypus*, Oppel.); *Ephthianura*, Gould (*Acanthiza*, J. and S.); *Anthus*, Bechst.; *Corydalla*, Vig. (*Anthus*, Vieill.). [MOTACILLINÆ.]

Of these names, *Petrophila* and *Wilsonia* are terms employed in botany.

The Sylviadæ, in Mr. G. R. Gray's arrangement, are followed by the Turdidæ. ('List of the Genera of Birds.')

We shall illustrate this family by describing some forms which are not found in other parts of this work.

The genus *Phenicura*, to which the Common Redstart belongs, may be regarded as typical of this family. The beak is slender and nearly straight, compressed towards the point, slightly deflected, and emarginated; nostrils basal, lateral, oval, pierced in a membrane, and partly concealed by the feathers of the forehead; wings of moderate size, the first quill very short, the second equal in length to the sixth, the third, fourth, and fifth nearly equal, but the fourth the longest; tail more or less red in all the species; legs with the tarsus lengthened and slender, longer than the middle toe; outer toes nearly equal in length.

P. ruticilla, the Common Redstart. It is the *Motacilla Phenicura* of Linnæus. Belon is of opinion that this is the *φωκίκοπος* of Aristotle ('Hist. Anim.' ix. 49). It is the Corossolo, Codiroso, Culo Ranzo, and Culo Rosso of the Italians; Rossignol de Mur ou de Mraillles of the French; Schwarzkehliger Sanger, Schwarzkehllein,

and Garten-Rothschwänzen of the Germans; Gekraagde Roodstart of the Netherlands; Rodstjert of the Swedes; Roedstiert of the Danes; Blodfugl of the Norwegians; Rhonell Goeh of the Welsh; Redtail, Brantail, and Firetail of the English.

The old male has the forehead and eyebrows pure white; a small band on the root of the bill, space between that and the eye, throat, and upper part of the neck, deep black; head and upper part of the back bluish ash; breast, sides, rump, and lateral tail-feathers, brilliant ruddy; abdomen whitish, lower coverts of the tail deep ruddy, two middle feathers brown.

The female (which may easily be confounded with that of *P. Suecica*, the Blue-Throated Warbler) with the upper parts gray strongly shaded with rusty; great wing-coverts bordered with ruddyish yellow; throat white, breast and sides rusty, belly whitish, under tail-coverts pale rusty. The very old have the throat blackish, spotted with rusty.

The young males of the year have no white on the forehead; black of the throat broken with whitish lines; ruddy colour of the breast varied with white; upper parts rusty ash, tail-coverts and feathers bordered with rusty.

The young females may be distinguished from the nightingale by the black bill and feet, and the two middle tail-feathers, which are always blackish-brown.

This bird is found in Denmark, Norway, Sweden, Russia, Europe generally, particularly Holland, France, Provence, Spain, and Italy. Trebizond, and to the south-east of that locality, Erzerum, and Japan.

In Britain it arrives about the middle of April, penetrating as high as Sutherlandshire in Scotland. Pennant says that it extends no farther west than Exeter, but it has been seen in the eastern portion of Cornwall, and is far from uncommon in the western part. The Welsh name above given, from Pennant, indicates that the bird must have been formerly known in Wales: it certainly is now, and has even been found near Belfast in Ireland; but this appears to be a singular instance. They quit England generally at the commencement of September.

Redstart (*Phenicura ruticilla*).

Lower figure, male; upper figure, female.

The Redstart is a sweet and indefatigable singer, and has been heard in a wild state as late as ten o'clock at night, and as early as three o'clock in the morning. The skirts of woods, lane and meadow hedge-rows, orchards, gardens, the old ivied-wall of a ruin, are all favourite haunts. The male shows himself, as if proud of his pretty plumage, whilst he is uttering his soft, sweet song, vibrating his tail the while, on some low branch of a not high tree, or weather-beaten stone, nor does his music cease as he flies to another station to continue his strain.

A crevice in a wall, a hollow tree, a nook in a building sheltered

behind a limb of ancient ivy, or even of an old fruit-tree trained against it, sometimes a hole in the ground, receives the nest, the outside of which is rough and rich with moss, and lined with hair and feathers. Four, six, and even eight greenish-blue eggs are deposited, and the first brood, for there are generally two in a season, are frequently fledged by the second week in June. The food consists of worms and insects, fruit, and berries.

Bechstein speaks highly of its attractive qualities in plumage, gesture, and song; and says it will add to its natural notes parts of the songs of other birds. He tells us that those which built under his roof imitated tolerably the chaffinch that hung in a cage at his window; and his neighbour had one in his garden that repeated the strains of a black-cap which had its nest near.

In captivity Redstarts become so tame that they will take a meal-worm from the hand. Sweet says that, when kept in confinement, he considers this bird the most sensible, and, if brought up from the nest, the most attached of all small birds; but he adds that it may be deemed the most tender of all the tribe. It is, he observes, a real mocker, and, if bred up from the young state, will learn the note or call of almost any other bird: it will also learn a tune, and will sing by night as well as by day, as long as a light is kept burning. He had one that whistled the Copenhagen Waltz.

The 'Portraits des Oyseaux' has the following quatrain under the cut of this Wall Nightingale:—

"Ce Rossignol est nommé de muraille,
Pource qu'es murs il bastit sa maison,
Fait ses petits: mais en comparaison
Au Rossignol, il ne dit rien qui vaille."

Notwithstanding the censure involved in the last line and a half however the Redstart is a very charming songster. In comparison with the nightingale, every other bird's song must fade.

Melizophilus has a slender beak, upper mandible slightly bent from the base and finely emarginated near the tip; under mandibles straight, shorter than the upper, and shutting within it; nostrils basal, lateral, cleft longitudinally; base of the beak surrounded with hairs. Wings short, the first quill-feather very small, the second shorter than either of the next four feathers; the fourth and fifth the longest in the wing. Tail elongated, cuneiform. Tarsi strong, and longer than the middle toe; claws of moderate length, sharp.

Dartford Warbler (*Melizophilus Dartfordiensis*).
Upper figure, male; lower figure, female.

M. Dartfordiensis, the Dartford Warbler. It is the Pitte-Chou de Provence of the French; the Magnauina of Savi; and Provenser Sanger of Meyer.

The old male has all the upper parts, with the exception of the tail, fine deep-gray; throat, breast, and sides, purple-reddish, or the colour of wine-lees; middle of the belly white; tail very long, blackish-brown, the external feather only terminated with white: quills ash-coloured externally, but black on the internal barbs; wings very short; feet yellowish; bill black, but yellowish-white at its base; iris brown. Length 5 inches.

The female has the tints generally less vivid than those of the male; on the throat a greater number of fine whitish stripes than in the male, which, when old, presents hardly any traces of them.

The young of the year have a great number of small stripes on the throat, the lower parts varied with whitish feathers. (Temm.)

This bird is found in southern Europe, the countries that border the Mediterranean, Spain, and the south of Italy, but Prince C. L. Bonaparte notes it as rare, and as found in summer in mountainous situations. It is comparatively scarce in Germany and Holland. Permanent in England, but not generally diffused. Frequent in the neighbourhood of London, and also at Bagshot, Chobham, and their vicinities. Devonshire, Cornwall, and Berkshire, possess it also.

The furze-brake and tangled heath are its favourite haunts. Mr. Gould observes, that its form closely allies it to the Superb Warblers (*Malurus*) of Australia, while its relationship to the Common White-throat is strikingly apparent. With reference to its secluded habits, the same author well remarks that in the spring it becomes more lively and more frequently visible, "rising on quivering wing above the tops of the furze, and uttering a hurried habbling song, much after the manner of the Whitethroat; at these times it erects the feathers of the head into a crest, and distends the throat, exhibiting many attitudes and gestulations."

Dry stalks and grass intertwined with fibres of plants and roots form the nest, which is generally snugly bid in the very heart of a thick furze-bush not far from the ground. Eggs greenish-white, with brown speckles and ashy spots, and thus resembling those of the Whitethroat.

The Dartford Warbler is, generally speaking, insectivorous, but fruits do not come amiss to it, that is, such berries as it may find near its retreats.

Sylvicola.—This genus is well-represented by the Myrtle Bird of America.

S. coronata, the Yellow-Crowned Warbler, or Myrtle-Bird. In summer plumage it is blackish slate-colour, streaked with black; beneath white; breast spotted with black; crown, sides of the breast, and rump, yellow; wings bifasciated with white; tail black; three lateral tail-feathers spotted with white. Winter plumage edged with brownish-olive, the yellow of the crown partly concealed by a margin of the same olivaceous hue; no black on the head or face.

Young browner, the yellow much paler and nearly without black. Length from 5 to 6 inches; alar extent from 8 to 9 inches.

It arrives in the Middle and Northern states of the Union from the south towards the end of April or beginning of May, and then probably passes north to breed. In August they re-appear in those states, and remain about the gardens and woods till about the end of November, feeding almost exclusively at this period on the Myrtle-Wax Berries (*Myrica cerifera*), or those of the Virginian Juniper. "These," says Mr. Nuttall in continuation, "with other late and persisting berries, and occasional insects, constitute their winter food in the Southern States, where, in considerable numbers, in the swamps and sheltered groves of the sea-coast, they pass the cold season. In fine weather, in the early part of October, they may be seen at times collecting grass-boppers and moths from the meadows and pastures, and, like the Blue-Bird, they often watch for the appearance of their prey from a neighbouring stake, bough, or fence-rail; and at this time are so familiar and unsuspicious, particularly the young, as fearlessly to approach almost within reach of the silent spectator. At the period of migration they appear in an altered and less brilliant dress; the bright yellow spot on the crown is now edged with brownish-olive, so that the prevailing colour of this beautiful mark is only seen on shedding the feathers with the band; a brownish tint is also added to the whole plumage; but Wilson's figure of this supposed autumnal change only represents the young bird. The old is, in fact, but little less brilliant than in summer, and I have a well-founded suspicion that the wearing the edges of the feathers, or some other secondary cause, alone produces this change in the livery of spring, particularly as it is not any sexual distinction. While feeding, they are very active, in the manner of Flycatchers, hovering among the cedars and myrtles with hanging wings, and only rest when satisfied with gleaming food. In spring they are still more timid, busy, and restless. Of their nest we are wholly ignorant. When approached, or while feeding, they only utter a feeble plaintive 'tship' of alarm. This beautiful species arrives here about the 7th or 8th of May, and now chiefly frequents the orchards, uttering, at short intervals, in the morning, a sweet and varied, rather plaintive warble, resembling in part the song of the Summer Yellow-Bird, but much more the farewell, solitary, autumnal notes of the Robin Redbreast of Europe. The tones at times are also so ventriloquial and variable in elevation,

that it is not always easy to ascertain the spot from whence they proceed. While thus engaged in quest of small caterpillars, it seems almost insensible to obtrusion, and familiarly searches for its prey, however near we may approach." ('Manual')

Yellow-Crowned Warbler (*Sylvicola coronata*).

S. astiva, the Summer Yellow-Bird, is remarkable for its skilful prevention of the designs of the Cow Troopial. [MOLOTHRUS.] "It is amusing," says Nuttall, "to observe the sagacity of this little bird in disposing of the eggs of the vagrant and parasitic Cow Troopial. The egg, deposited before the laying of the rightful tenant, too large for ejection, is ingeniously incarcerated in the bottom of the nest, and a new lining placed above it, so that it is never hatched to prove the dragon of the brood. Two instances of this kind occurred to the observation of my friend Mr. Charles Pickering, and last summer I obtained a nest with the adventitious egg about two-thirds buried, the upper edge only being visible, so that in many instances it is probable that this species escapes from the unpleasant imposition of becoming a nurse to the sable orphan of the Cow-Bird. She however acts faithfully the part of a foster-parent when the egg is laid after her own."

Ephianura is an Australian genus.

E. albifrons, White-Fronted Ephianura. The male has the forehead, face, throat, and all the under surface pure white; occiput black; chest crossed by a broad crescent of deep black, the points of which

White-Fronted Ephianura (*Ephianura albifrons*), male. (Gould.)

run up the sides of the neck and join the black of the occiput; upper surface dark-gray with a patch of dark-brown in the centre of each

feather; wings dark-brown; upper tail-coverts black; two centre tail-feathers dark-brown, the remainder dark-brown, with a large oblong patch of white on the inner web at the tip; irides in some beautiful reddish-buff, in others yellow with a slight tinge of red on the outer edge of the pupil; bill and feet black.

The female has the crown of the head, all the upper surface, wings and tail grayish-brown, with a slight indication of the oblong white spot on the inner webs of the latter; throat and under surface buffy-white; a slight crescent of black on the chest. (Gould.)

Mr. Gould first met with this species in a state of nature on the small islands in Bass's Strait, where, he says, it had evidently been breeding, as he observed several old nests in the Barilla and other stunted bushes which clothe other isolated spots, particularly chalky and green islands immediately contiguous to it in Flinders. He did not observe it in Van Diemen's Land or to the southward of the localities above mentioned. He thinks however that it extends over the whole of the southern portion of the Australian continent, for he has specimens which were killed at Swan River, in South Australia, and in New South Wales. The extent of its range northward is not, he remarks, known. He had never seen examples from the north coast.

Curruca has a short rather stout bill, upper mandible slightly curved at the point, which is emarginated; gape with a few hairs. Nostrils basal, lateral, oval, exposed. Wings of moderate size; the first quill-feather very short, the second longer than the fifth, the third the longest in the wing. Legs with the tarsus short, but longer than the middle toe; the toes and claws short, and formed for perching.

C. cinerea, the Whitethroat; *Motacilla sylvia* and *Sylvia cinerea* of authors. It is the Fauvette Grise, or Grisette, of the French; Macchietta and Sterpazzola of the Italians; Klapper Grasmücke, Fable, Grauliche, Rostgrau, and Grauköpfige Heekengrasmücke of the Germans; Kogsnetter and Mesar of the Swedes; Common Whitethroat, Muggy, Muggy-Cut-Throat, Whey-Beard, Wheatie-Why-Bird, Muff, Charlie Muftie, Peggy, Peggy-White-Throat, Churr, and Wbautie of the English; and Y Gwddfgwyn of the Welsh.

The male has the top of the head and space between the eye and the bill ash-colour; other parts gray, strongly tinged with rust-colour, which last predominates principally on the top of the back; wings blackish, all their coverts bordered with very bright rusty; quills edged with this colour, except the external one, which is edged with white; throat and middle of the belly pure white; breast slightly tinged with rose-colour; sides and abdomen rusty-gray; tail deep-brown; quills of equal length, except the most external, which is much the shortest; this last has the outside barb and the extremity pure white; the succeeding feather is only terminated with whitish. Length 5 inches.

The female has the tints less pure and the upper parts more clouded with rusty; white of the throat and of the external tail-feather clouded with rusty; no rosy tinge on the breast.

The young have more rust-colour on the upper parts; space between the eye and the bill white, and the rusty borders of the wing-coverts wider; external quill edged with rusty instead of white.

This bird is found in Denmark, Norway, Sweden, Russia, Siberia, Germany, Holland, France, Provence, Spain, Sardinia, Italy, Smyrna, Trebizond. It is a regular summer visitor to the British Islands, arriving about the third week in April, and departing in autumn.

Common Whitethroat (*Curruca cinerea*).

The principal food of the Whitethroat consists of insects: it is very fond of caterpillars, and is a considerable consumer of berries and smaller garden-fruits, such as raspberries, currants, &c., among which they and their young make much havoc in July and August. A dwarf

hush or a low tangled thicket of brambles, nettles, weeds, and rank grass, is generally selected for the nest, which is seldom found at a greater distance from the ground than 2 or 3 feet, and has the outside framed almost entirely of the stems of dried grass. The upper part or cup of the nest is very thin and flimsy at the sides, and the inside is lined with finer grass stalks and panicles. The eggs, which amount to four or five, are white with a greenish tinge, speckled and spotted with ashy-brown and ashy-green of two shades.

C. garrula, the Lesser Whitethroat. It is the *Sylvia Curruca* of Latham and authors; Fauvette Babillarde of the French; Fichten, Doon, and Kleinschnäbige Klappergrasmücke of the Germans; Bigiarella of the Italians. The whole of the top of the head is of a pure ash-colour; space between the eye and the bill and feathers that cover the orifice of the ears deeper ash; uape, mantle, and rump, ashy-brown; tail blackish, external feathers ash-colour, bordered and terminated with white, but white on the whole of the external barb; the two next feathers only terminated by a small white spot; the breast, sides, and abdomen, white slightly tinged with rusty; the rest of the lower parts pure white. Length 5½ inches.

The female not quite so large as the male, which has been seen in two instances with a beautiful tinge of carmine on the breast. It is found in Denmark, Sweden, Russia, and the temperate and warmer parts of Europe, Asia, and the Deccan of Hindustan. In these islands it is rare as far north as Northumberland, and rarer in Scotland. In Ireland it does not appear to have been seen. It arrives and departs about the same time as the Common Whitethroat.

In Germany it is termed Das Müllerchen, or the Little Miller, from some of its clacking tones being supposed to resemble the noise of a mill, according to Bechstein, who remarks that, as these notes are heard more distinctly than the others, they are erroneously thought to be its whole song; but the rest, he adds, though certainly very weak, is so soft, so varied, and so melodious, that it surpasses other warblers. Whilst singing in this under-tone, says Bechstein in continuation, it is continually hopping about the bushes; but when going to utter 'clap, clap,' it stops and employs the whole strength of the larynx to pronounce this syllable. To enjoy the beauty of its song, Bechstein remarks that it should be alone in a room, and then no other singing-bird is more agreeable, as it rarely utters its call. Both Sweet and Blyth speak favourably of its song, though the former, who gives a very pleasing account of one which he bred up from the nest, says it is not so agreeable as that of most of the other species of warblers.

C. hortensis, Greater Pettychaps, is the *Sylvia hortensis* and *Motacilla hortensis* of authors; the Beccafico of the Italians. [BECCAFICO.]

The whole of the upper parts is oil-green, with a shade of ash-gray; on each side of the lower part of the neck is a patch of ash-gray; throat grayish-white; breast and flanks yellowish-gray, inclining to wood-brown; belly and vent grayish white; orbits of the eyes white; sides brown; bill wood-brown; legs and claws bluish-gray.

The female is similar in plumage to the male bird.

The young of the year have the region of the eyes grayish-white; head, upper part of the neck, hack, rump, and wing-coverts, yellowish-brown, passing into oil-green; quills greenish-gray, edged with oil-green; cheeks and sides of neck yellowish-gray; throat, breast, sides, and under tail-coverts, wine-yellow; middle of the belly white; legs, toes, and claws, pearl-gray. (Selby.)

Greater Pettychaps (*Curruca hortensis*).

The Greater Pettychaps seems to have been first described as a British species by Latham, who received it from Sir Ashton Lever. The bird was obtained in Lancashire. It has since become better known, and its arrival with the other warblers in April and May has been regularly noticed. Montagu, who observes that he traced it through the greater part of England, fixes the Tyne as its northern

NAT. HIST. DIV. VOL. IV.

boundary; but he is corrected by Selby, who says, "I have often seen it on the north of the river Tweed."

All who have heard the bird agree in their praise of its song, which is little inferior to that of the nightingale. Montagu states that it frequently sings after sunset. "Some of the notes," says that ornithologist, "are sweetly and softly drawn; others quick, lively, loud, and piercing, reaching the distant ear with pleasing harmony, something like the whistle of the blackbird, but in a more hurried cadence." Selby corroborates this, observing that its song, although inferior in extent of scale, almost equals that of the nightingale in sweetness. It is seldom seen; for, like the rest of the tribe, it haunts the shaded coverts, and usually sings from the midst of some close thicket. Lewin says that it makes its nest for the most part with fibres and wool, sometimes with the addition of green moss, often in the neighbourhood of gardens, which it frequents, with the White-Throat and Black-Cap, for the sake of currants and other fruits. Montagu, who has recorded this habit, states also that it inhabits thick hedges, where it makes a nest near the ground, composed of Goose-Grass (*Galium Aparine*, Linn. and other fibrous plants, flimsily put together, like that of the common Whitethroat, with the addition sometimes of a little green moss externally. Selby gives much the same description. It lays four, sometimes five eggs, about the size of a hedge-sparrow's, or hedge-warbler's, of a dirty-white, blotched with light brown (Selby says wood-brown), the blotches being most numerous at the larger end. Its alarm-call, according to Selby, is very similar to that of the White-throat. Early in September it leaves us, and Prince Bonaparte notes it as common near Rome in the autumn.

Sylvia has a straight beak, slender, conical, pointed, slightly notched at the tip, sides compressed, base furnished with fine hairs; nostrils basal, lat-ral, oval. Wings with the first quill very short, the second shorter than the third, the third the longest in the wing. Legs with the tarsi longer than the middle toe; toes three before, one behind; the outer toe jointed at the base to the middle toe.

S. sylvicola, the Wood-Warbler, or Wood-Wren. It is the *Motacilla trochilus* of Bewick; *Sylvia sibilatrix* of Bechstein; *Curruca sibilatrix* of Wood; Bec-fin Siffleur of Temminck; La Fauvette Sylvicole of Vieillot; Lui Verde of Savi; Grüner Säuger of Meyer; and Schwirrender, Grossschnäbliger, und Nordischer Laubvogel of Brehm.

Mr. Yarrell, after tracing the steps of its history as a British bird through the works of White of Selborne, Pennant, and Montagu, observes that the bird is now very well known, and is at once distinguished from the True *Trochilus*, or Willow-Warbler, with which it is most likely to be confounded, by the broad streak over the eye and ear-coverts of bright sulphur-yellow, by the pure-green colour of the upper parts of the body, and by the delicate and unsullied white of the belly and under tail-coverts.

Wood-Wren (*Sylvia sylvicola*).

In addition to these distinctions, which, Mr. Yarrell observes, on comparing the two birds, will be found very obvious, he points out the fact that the wing of the Wood-Warbler is nearly half an inch longer from the carpal joint to the end of the quill-feathers than that of the Willow-Warbler, although the birds themselves differ but little in their respective whole lengths; the wings of the Wood-Warbler, when closed, reaching over three-fourths of the length of the tail, while those of the Willow-Warbler reach only to the end of the upper

tail-coverts, or less than half way along the tail-feathers. The two birds here named, and a third species, the Chiff-Chaff, so called from its peculiar note, are, Mr. Yarrell remarks, the only British species included in the genus *Sylvia* as at present restricted. These, he states, differ from the Warblers generally in the colour of their plumage, and in not being fruit-eaters. Their nests are covered or domed at the top.

It is a Swedish summer visitor, but rare there, as it is in northern Europe generally. Of frequent occurrence in Germany, Holland, France, Provence, and Italy, in the summer. It is found in England and Wales, but not recorded in Scotland nor identified in Ireland. Supposed winter-quarters, Egypt and Asia.

The song, if sung it may be called, of this species is to be heard in the woodlands of England and Wales in the spring, and during the greater part of the summer, accompanied by a shivering of the wings. Mr. Yarrell well describes the note as resembling the word 'twée,' sounded very long, and repeated several times in succession, at first but slowly, afterwards much quicker, and as accompanied, when about to conclude, by a peculiar tremulous motion of the wings, which are lowered by the side. A lofty elm in a hedgerow is often, he observes with equal truth, selected as the singing station, and the note is occasionally uttered while the bird wings its way from place to place.

Insects and their larvæ form its food, which is captured both on the wing and among the leaves of trees. The oval and domed nest is framed, amid the herbage on the ground, of dry grass, leaves, and a little moss, with a finer lining of grass and hairs, but no feathers, which last are present in the nests of other warblers that build on the ground, with the exception of the other two *Sylvia* noticed above. The white eggs, most thickly speckled with purple-red and ash, are generally six in number.

The following is a list of the British species of this family, as given in Yarrell's 'British Birds':—

Acentor alpinus, Alpine Accentor.
A. modularis, the Hedge Accentor, or Hedge-Warbler.
Erythaca rubecula, the Redbreast, or Robin. [ERYTHACA.]
Phenicura Suecica, the Blue-Throated Warbler. [BLUE-BREAST.]
P. ruticilla, the Redstart. [MOTACILLINÆ.]
P. tithys, the Black Redstart.
Saxicola rubicola, the Stonechat. [SAXICOLA.]
S. rubetra, the Whinchat. [SAXICOLA.]
S. ananthe, the Wheatear. [SAXICOLA.]
Salicaria locustella, the Grasshopper Warbler. [SALICARIA.]
S. phragmites, the Sedge Warbler. [SALICARIA.]
S. luscinioides, the Salvia Warbler. [SALICARIA.]
S. arundinacea, the Reed Warbler. [SALICARIA.]
Philomela lusciniæ, the Nightingale. [PHILOMELA.]
Curruca atricapilla, the Black-Cap Warbler. [CURRUCA; BLACK-CAP.]

C. hortensis, the Garden Warbler.
C. cinerea, the Common Whitethroat.
C. sylvicola, the Lesser Whitethroat.
Sylvia sylvicola, the Wood Warbler.
S. trochilus, the Willow-Warbler.
S. hippolais, the Chiff-Chaff.

Melospiza Dartfordiensis, the Dartford Warbler.
Regulus cristatus, the Golden-Crested Regulus. [REGULUS.]
R. ignicapillus, the Fire-Crested Regulus. [REGULUS.]
R. modestus, the Dalmatian Regulus. [REGULUS.]

(Yarrell, *History of British Birds*.)

SYLVICAPRA. [ANTHROPUS.]

SYLVICOLA. [SYLVIA.]

SYLVIPARUS. [SYLVIA.]

SYMA. [HALCYONIDÆ.]

SYMMORPHUS (Gould), a genus of Birds. The bill is rather short, tumid; the upper mandible slightly notched at the tip; the culmen and commissure subarcuate; the nostrils basal, oval, and nearly hidden by the frontal feathers. Wings moderate; first quill shorter than the second by one-half; third, fourth, and fifth longest and nearly equal. Tail moderate, the external tail-feather on each side shorter than the rest by one-fourth. Tarsi and feet moderate, the former scutellated anteriorly; the posterior toe with its claw shorter than the middle one, the two lateral toes unequal, the inner shortest. *S. leucopygus* is a native of Australia.

SYMPATHETIC NERVES. [NERVOUS SYSTEM.]

SYMPHORICARPOS, or SYMPHORIA, a genus of Plants belonging to the natural order *Caprifoliaceæ*. The tube of the calyx is globose, with a small limb, and 4-5-toothed; corolla funnel-shaped, 4-5-lobed; stamens 5; ovary 4-celled, with simple style and semi-globose stigma, the fertile cells containing one ovule, sterile ones several; fruit a berry, having 4 cells, 2 of which contain single seeds and 2 are empty. The species are natives of North and South America. They are elegant, bushy, oppositely-branched shrubs, with oval entire leaves, small white or rose-coloured flowers with short pedicels, seated on one or many-flowered peduncles, and furnished with two bracts.

S. vulgaris, Common St. Peter's-Wort. Flowers disposed in axillary capitate clusters, and seated on very short pedicels. It is a native of Pennsylvania, the Carolinas, and Virginia, in sandy dry districts. It

bears red cup-shaped berries, which are about the size of a hempseed, and ripen in winter. It grows to the height of from 3 to 6 feet, and flowers in August and September.

S. racemosus, Snow-Berry. Flowers disposed in loose, often leafy, interrupted racemes; corolla bearded internally; stamens and style included. It is a native of North America, and grows on the banks of the Missouri, in Upper Canada, and on the north-west coast at Paget's and Nootka Sound. This is a very handsome shrub, and was introduced into our gardens in 1817, since which time it has become very common. It has rose-coloured flowers, with entire leaves glaucous beneath. The fruit is about the size of a small cherry, and quite white, remaining on the tree after the leaves have dropped off, and giving it a very beautiful appearance.

S. occidentalis, Wolf-Berry, Western St. Peter's-Wort. Flowers in spikes, dense, terminal, axillary, and drooping; style and stamens protruded. It is a native of British North America, and is abundant about the Saskatchewan and Red River. It is a shrub from 4 to 6 feet high, and has the same general characters as the last, but has not yet been cultivated in Great Britain.

S. microphyllus and *S. glaucescens* are natives of Mexico.

SYMPHYNOTA. [NAIADÆ.]

SYMPHYTUM, a genus of Plants belonging to the natural order *Boraginaceæ*. It has a 5-parted calyx; a cylindrical-campanulate corolla, the throat of which is furnished with 6 eubulate vaulted processes which connive to form a cone; 4 1-celled ovate nuts fixed at the base of the calyx, imperforate. The species are rough herbaceous plants, with broad leaves and terminal twin racemes of flowers. They are natives chiefly of Europe and Asia.

S. officinalis, Common Comfrey. Fusiform-branched roots; branched stem; leaves decurrent, the upper ones lanceolate, the lower ovate-lanceolate, scabrous above and hairy beneath; limb of the corolla 3-toothed, with the teeth recurved; the anthers twice the length of the filament. It is an inhabitant of the banks of rivers and streams and watery places throughout Europe. "Comfrey-root," Woodville observes, "abounds in a tasteless mucilage like that of the marsh-mallow; and being more easily obtained, it ought not to be omitted in lists of medicinal plants." The flowers are of a yellowish-white colour. A variety not uncommon in Scotland and the continent has bluish-purple flowers, red before expansion: it was called by Sidthorp *S. patens*. *S. Bohemum* is also a variety of this species. It has red or reddish-purple flowers.

S. tuberosum, Tuberous-Rooted Comfrey. Rhizoma oblique, thickened by scales, furnished with short branches; leaves partly decurrent, upper ones elliptical, lower ones ovate; corolla tubulose, funnel-shaped, 5-toothed; teeth recurved. This plant is not so stiff and hairy as the last. It is a native of Germany, Austria, France, Spain, and Italy. It has also been found in Scotland near Edinburgh, and in Durham in England. Its flowers are of a yellowish-white colour, and appear in April and May.

S. aspernum, Rough Comfrey. Stems branched, covered with tubercles; leaves ovate, heart-shaped, pointed, running into petioles, hairy above, strigose beneath, upper ones opposite, subsessile; calyx tuberculated, acute; limb of corolla campanulate. It is a native of the Caucasus, and grows on the banks of streams and rivulets. It is a tall plant, very rough, with handsome flowers, which are red before expansion, and afterwards blue. There are several other species.

SYMPLECTES. [PLOCINÆ.]

SYMPLESITE. [IRON.]

SYMPLOCARPUS, a genus of Plants belonging to the natural order *Araceæ*. It has a cucullate spathe, a short spadix covered with tetrandrous floscules. The ovaries are 1-celled, with an ovule in each and a minute stigma; berries consolidated; seeds without albumen.

S. fatidus, Skunk-Weed, or Skunk-Cabbage, has a large abrupt tuber with numerous crowded fleshy fibres; the spathe is precocious, ovate, turgid, various in width, spotted, and sometimes covered with dull brownish purple; the spadix is oval, on a short peduncle covered with perfect tetrandrous flowers, and of the same colour as the spathe. It has 4 fleshy wedge-shaped sepals, truncate at the top, and edges inflated; the 4 stamens are opposite the sepals, with subulate filaments equal in length to the calyx. When the spathe decays, the spadix continues to grow, and every part of the plant, excepting the anthers. Within the spadix at the base of each style is a round fleshy seed as large as a pea, white, tinged with green and purple, and invested with a separate membranous coat, and with a prominent embryo situated in a depression at the top. The leaves spring up some time after the flowers; they are numerous, large, crowded, oblong, heart-shaped, and on long channelled petioles. The plant emits an offensive odour; its tubers are acrid, but when dried and powdered are antispasmodic.

(Lindley, *Flora Medica*.)

SYMPLOCOS (from *συνπλοκή*, a knitting together), a genus of Plants belonging to the natural order *Styracaceæ*. This genus was made the type of a natural order, *Symplocineæ*, by D. Don, which contained only this example. It has a 3-parted half-inferior calyx; rotate monopetalous 3-10-parted corolla, imbricate in æstivation; indefinite stamens inserted in the lobe of the corolla, with the filaments cuspidate at the apex, and polyadelphous at the base; erect anthers bursting longitudinally; 3-5-celled ovary with 4 ovules in each cell.

The fruit is a fleshy drupe, containing a 3-5-celled nut; the cells containing but one seed, which has an inverted embryo lying in albumen, and a superior radicle. The species are trees, having alternate either entire or serrated leaves without stipules, and turning yellow in drying. The flowers are axillary, sessile, or pedunculate, few, of a white or scarlet colour, and supplied with bractæ as at their base. Upwards of 30 species have been described. They all possess an astringent principle in their leaves, and some are used in dyeing.

S. Alstonia, Alston's Symplocos, is the *Alstonia theaformis* of Linnæus, and was named after Charles Alston, professor of botany in the University of Edinburgh. The plant is glabrous in every part, and has shining coriaceous roundish-elliptic or oblong leaves, obtuse, rounded at the base, and obscurely crenated at the apex. Sessile flowers arranged in threes and fours. It is a native of New Granada, near Santa Fé de Bogota, and Popayan.

S. tinctoria, Dyer's Symplocos, Sweet-Leaf, Yellow-Leaf. Leaves oblong or lanceolate ovate, serrated, glaucous, shining; flowers axillary, 8 or 16, together. This plant is the *Ilopa tinctoria* of Linnæus, and is a native of the Carolinas, in the United States of America.

S. racemosa, Racemose-Flowered Symplocos. Leaves oblong, glabrous, serrated; flowers arranged in racemes, mostly axillary; nut of fruit 3-celled. This plant is a native of Burdwar and Midnapore, in Bengal. It is used extensively by the natives as a red dye.

The nuts of *S. spicata* are very hard, and resemble a little fluted pitcher. This plant is a native of Silhet.

SYNÆTHERES. [HYSTRICIDÆ.]

SYNALLAXIS, M. Vieillot's name for a genus of Birds placed by Mr. Swainson in the family *Certhiidae*. The bill is short, rather

Synallaxis garrulus (reduced from Mr. Swainson's figure).

Nest in tree (after the same).

strong, straight; both mandibles of equal thickness, entire, and much compressed; the margins of the upper mandible inflexed beyond the nostrils. Frontal feathers rather rigid. Wings very short, and much rounded; the primaries scarcely exceeding the tertials. Tail broad, more or less lengthened, and either graduated or cuneated; the webs soft and loose, but the shafts rather rigid; the tips lanceolate. Feet very large; tarsus lengthened; middle toe longer than the hinder; lateral toes equal; claws slender, acute, and but slightly curved; the three anterior rather small. (Sw.)

S. garrulus is brown, whitish beneath; feathers on the front of the head rigid, pointed, and rufous; lines before and behind the eye whitish. Tail moderate, rounded.

It is remarkable for its very singular nest, which is so large as to form a feature in the woodland scenery of Bahia. The nest is built in low trees, formed externally of dried sticks, without any neatness, usually three or four feet long, and resembling at a distance a thick twist of bean-stalks thrown in the branches by accident. Sometimes two of these nests appear as if joined together, and there is an opening on the side, besides one at the top.

SYNAPTÆ, a family of *Echinodermata*, belonging to the order *Holothuriadae*. It is characterised in this order by the absence of suckers. It is represented in the British seas by the genus *Chirodota*, which has a cylindrical and vermiform body, elongated tentacula, digitate at their extremities.

C. digitata has a vermiform body, white with orange spots, the tentacula long, pedunculated, digitate. This animal was first found by Montagu on the shores of South Devon. It is very rare. Professor E. Forbes, in his 'History of British Star-Fishes,' says that he had never seen a living specimen.

SYNBATHO'CRINUS. [ECHINODERMATA.]

SYNDACTYLES, a group comprehending those Birds which have the external toe nearly as long as the middle one, and united to it as far as the penultimate articulation. This group contains the Bee-Eaters (*Merops*, Linn.), the Motmots (*Prionites*, Ill.), the King-Fishers (*Alcedo*, Linn.), the Todies (*Todus*, Linn.), and the Hornbills (*Buceros*, Linn.).

SYNEDRA. [DIATOMACEÆ.]

SYNETHERES, or SYNÆTHERES. [HYSTRICIDÆ.]

SYNGNATHA, according to Dr. Leach, the second order of the class *Myriapoda*, comprising the species of that class which were by Linnæus included under the head *Scolopendra*.

This order is divided by Latreille into two sections. The species of the first have only 15 pairs of legs, and the body when viewed from above presents less segments than when viewed from beneath; in the second section there are at least 21 pairs of legs, and the segments are of the same size and number both above and beneath. Dr. Leach also divides the present order into two sections or families, to which he applies the names *Scolopendridæ* and *Geophilidæ*, which he characterises as follows:—The first (*Scolopendridæ*) have each segment of the body provided with two legs, and the hinder legs distinctly longer than the others. To this family belongs the *Scolopendra forficata* of Linnæus, a species found commonly under stones, &c., in this country and other parts of Europe. According to the author last mentioned, this species constitutes the type of his genus *Lithobius*, distinguished by the antennæ being composed of 40 or more joints, the two first of which are the largest; the under lip is broadly notched in front, and has the margin much denticulated; the eyes are granulated; the legs are 15 on each side. The genus *Cryptops* of Leach, of which a species (*C. hortensis*) is found in gardens in Devonshire, has about 17 joints to the antennæ; the under lip is not denticulated, and is scarcely emarginated in front; the legs are 21 on each side, and the first joint of the hinder legs is spineless; the eyes are indistinct.

In the family *Geophilidæ* the legs are very numerous, and the hinder legs are not distinctly longer than the others. The species of the genus *Geophilus* (Leach) have upwards of 40 legs, the antennæ having 14 joints. Several species are found in England. They live in the ground and under stones. The *Scolopendra electrica* of Linnæus belongs to this genus.

SYNGNATHIDÆ, a family of Fishes, embracing, according to some authors, the Pipe-Fishes, the Sea-Horses, and the Winged Sea-Horses. These forms are sometimes assigned to distinct families, as in the following definitions:—

Syngnathidæ, Pipe-Fishes.—Body prolonged, slender, linear, or angulated; snout greatly prolonged, cylindrical; mouth terminal, vertical. Ventral fins absent; caudal fin wanting in some.

Hippocampidæ, Sea-Horses.—Head and body compressed; snout narrow, tubular; mouth terminal. Pectorals small; dorsal single; caudal fin wanting.

Pegasidæ, Winged Sea-Horses.—Body broad, depressed; snout suddenly contracted, narrow, somewhat protractile; mouth terminal, beneath. Pectorals generally large; caudal fin small.

They all agree in having the endo-skeleton partially ossified; exo-skeleton ganoid; gills tufted (hence the group is named *Lophobranchia*), in the opercular aperture being small, and the swimming-bladder without an air-duct. We shall illustrate this family by a short description of the British species:—

Syngnathus has the body elongated, slender, covered with a series of indurated plates arranged in parallel lines. Head long; both jaws produced, united, tubular. No ventral fins.

In certain of the species the males are furnished with an elongated pouch under the tail; these are called marsupial, and include the British species *S. acus* and *S. typhle*.

S. acus, the Great Pipe-Fish, is one of the most common forms of the genus. It is found on many parts of the coast, sometimes at low-water amongst sea-weeds; at other times in deep water. The most curious feature in the economy of this fish is the fact that the roe is transferred from the belly of the female to the pouch of the male.

S. typhle (Linnaeus), the Deep-Nosed Pipe-Fish, Lesser Pipe-Fish, or Shorter Pipe-Fish; *Acus aristotelis* and *typhle antiquorum* of Willughby. This fish is distinguished from the last by the more compressed form of the jaws. From the British species it is distinguished by the possession on the part of the male of a pouch for the reception of the ova. The habits of this fish resemble those of the last.

S. equoreus, the Equoreal Pipe-Fish. This fish has no subcaudal pouch. It is comparatively rare on the British coast.

S. anguineus, the Snake Pipe-Fish. Although this and the preceding species possess no subcaudal pouch, the ova after exclusion from the female are carried by the male in separate hemispheric depressions on the external surface of the abdomen.

S. ophidion, the Straight-Nosed Pipe-Fish, is known by its straight nose. It is about nine inches in length.

S. lumbriciformis, the Worm Pipe-Fish, is the smallest of the British species. It has been taken on various parts of the coast. It does not exceed five inches in length. The young of this species have been observed to undergo a curious metamorphosis. On their escape from the egg the tail is covered with a fin-like membrane, and it also possesses pectoral fins. During their growth the caudal membrane and pectoral fins are absorbed.

Hippocampus.—The jaws are united and tubular, the mouth placed at the end. The body compressed, short, and deep. The whole length of the body and tail divided by longitudinal and transverse ridges, with tubercular points at the angles of intersection; both sexes have pectoral and dorsal fins; the female only have an anal fin; neither has ventral or caudal fins.

H. brevisrostris, the Sea-Horse, or Short-Nosed Hippocampus, is occasionally met with on the British coasts. The habits of these creatures are very singular. When swimming about they maintain a vertical position, but the tail is ready to grasp whatever meets it in the water. It quickly entwines in any direction round weeds or other objects, and when fixed the animal intently watches surrounding objects, and darts at its prey with great dexterity. When two are together they often twist their tails together. Their eyes move independently of each other, as in the chameleon.

Pegasus has a snout as in the previous genera, but the mouth is under it, and moveable. Two distinct ventral fins behind the pectoral, which are often large, hence the name of *Pegasus*, or Flying Horse. The species are found in Indian Seas.

(Yarrell, *History of British Fishes*; Adams, *Manual of Natural History*.)

SYNGNATHUS. [SYNGNATHIDÆ.]

SYNODONTIS. [SYLURIDÆ.]

SYNODUS. [ISOPODA.]

SYNOICUM, a genus of Ascidiæ, thus defined by M. De Blainville:—Body more or less cylindrical, vertical, or horizontal, adhering by the cephalic extremity, and united together by the sides of their external envelope, so as to constitute a common mass, which is a little diversiform and fixed; the two apertures of each composing animal hidden at the bottom of a more or less deep cavity, and having only a single external orifice, furnished ordinarily with six tentaculiform papillæ.

M. De Blainville thus divides the genus:—

A. Species united into a convex rounded mass. (*Pulmonella*, Lam.; *Aplidium*, Sav.) Ex. *S. ficus*.

Sycoicum Ficus. a, a portion highly magnified.

B. Species in which the horizontal bodies unite together in a mammillated crust. Ex. *S. subclatinozum*.

C. Species in which the vertical bodies also unite together in a crust. (*Didermum*, Sav.) Ex. *S. fungosum*.

D. Species in which the very long vertical bodies unite together in a species of cylinder, having only a single external orifice common to all the individuals.

Synoicum turgens.

M. De Blainville remarks that this genus, although very closely approximated to *Botryllus*, is really very distinct from it, in consequence of the manner in which the apertures of each composing animal terminate in a common cavity, with a single external orifice. He adds that it contains no more species than the genera above proposed, and that they appear all to belong to our seas. ('Malacologie.')

SYNOVIA, or Joint-Oil, is the name applied to the fluid by which the joints of the bodies of animals are lubricated. It is separated from the blood which circulates in the vessels immediately surrounding the joint. These form a very close capillary network in the tissue which bounds the cavity of the joint, and which, when it can be separated in a distinct layer, is termed the Synovial Membrane. [ARTICULATION.] Synovia is a pale yellow viscous fluid, which, when rubbed between the fingers, is peculiarly slippery, without being in any degree oily. In the horse, it was found by John (whose analysis is confirmed by those of several other chemists) to consist of—

Water	92.80
Albumen	6.40
Uncoagulable Animal Matter, with Carbonate and Hydro-Chlorate of Soda	0.60
Phosphate of Lime	0.15
Traces of Ammoniacal Salts and of Phosphate of Soda	0.05
	—100

Its quantity is in direct proportion to the size of the joint, and is always sufficient to keep the articular surfaces smooth and slippery, and to fill up those recesses in the joint into which the adjacent soft tissues do not exactly fit.

SYRINGA (from *σῦριξ*, a pipe), the name of a genus of Plants belonging to the natural order *Oleaceæ*. The English name of this genus, Lilac, is derived from 'lilag,' the Persian for a flower. It is known by a small 4-toothed calyx; funnel-shaped corolla, with a 4-parted limb; 2 stamens; a trifid stigma; a 2-celled, 2-valved, 2-seeded capsule; the valves boat-shaped, with a dissepiment in the middle. The species are natives of Europe and the colder parts of Asia. They are deciduous shrubs, with simple leaves, having purple or white flowers, which are arranged in beautiful thyrsoid terminal panicles, and are very fragrant.

S. vulgaris, the Common Lilac, known by its ovate heart-shaped pointed leaves. It is a native of Persia, Hungary, and the borders of the Danube. Dr. Sibthorp found it wild on Mount Hæmus, but not in Greece. This shrub has been long cultivated by the Turks, and was brought from Constantinople to Vienna by the ambassador Busbequius, in the middle of the 16th century, from whence it spread over the rest of Europe. It is now one of the commonest ornaments of our shrubberies, blossoming, together with the laburnum, in May. It is one of the few shrubs that resists the injurious influence of the smoke of cities, and flourishes in great perfection in most of the squares of London. It grows to the height of 20 feet and upwards, and sends up from the parent stem an abundance of suckers, which, if allowed to grow, form a dense mass of stems; these are commonly left, but if cut down as they are produced, the parent stem may be trained so as to grow as a small tree. It grows very fast, as much as from eighteen inches to three feet in the year, and endures, according to the soil, for twenty to fifty years. Several varieties are well known.

S. Josikea, *Josikas* Lilac, has elliptic-lanceolate, acute, ciliated, wrinkled, glabrous leaves, seated on short petioles, and white on the under surface, and purple flowers. It is a native of Transylvania, and was discovered by the Baroness von Josika, after whom it was named by Jacquin. It attains the height of six or eight feet, and has broad leaves, shining and dark green above and hoary beneath. It grows lu

damp shady places near water. Though very dissimilar in appearance to the common lilac, it has been suspected to be only a variety of that species. It is not yet very common in our nurseries.

S. Persica, the Persian Lilac. Leaves small, lanceolate. Flowers purple. It is a native of Persia, and is a small shrub, from four to six feet high. It is one of the most ornamental of low deciduous shrubs, and on that account is very commonly cultivated. When planted in pots and forced, it may be made to flower at Christmas; but by this process the fragrance of the flowers is lost. Of this species also three varieties are found in the nurseries, the White, the Cut-Leaved, and the Sage-Leaved Persian Lilacs.

S. Chinensis, Chinese Lilac. Leaves ovate-lanceolate. Flowers purple. It is a native of China. In character it is intermediate between *S. vulgaris* and *S. Persica*, and agrees with a hybrid plant produced at Ronen by M. Vain, and called *S. Rotomagensis*, the Rouen Lilac. It is a plant that grows vigorously, and attains a height of ten or twelve feet. The sorts known in nurseries as the Belgio Lilas de Marly and the Lilas Saugé are varieties of this species.

S. Emodi has elliptical-oblong leaves, glaucous beneath, attenuated at the base, and acuminate at the apex, with purple flowers. It is a native of Kumaon near the Himalayas. *S. villosa* has villous leaves, and is found in China on mountains about Peking, but neither of these species is cultivated in this country, although both would probably bear this climate.

Syringa is also the name that is commonly but improperly given to the species of *Philadelphus*, or Mock-Orange. The name *Syringa* was given to the Lilac on account of its stems being used for the manufacture of Turkish pipes. The stems of the *P. coronarius* are also used for the same purpose, and equally with the Lilac it had the name of Pipe-Privet, or Pipe-Tree, given it when first introduced into this country, and afterwards the name *Syringa*. [PHILADELPHUS.]

SYRINGODEA, a genus of Plants belonging to the natural order *Ericaceæ*. This genus was formed by David Don out of the old genus *Erica*. It possesses the following characters:—Calyx 4-leaved, glumaceous; corolla long, tubular, usually rather dilated at top, rarely a little contracted; limb short, 4-lobed; stamens for the most part inclosed, filaments capillary, anthers 2-parted, cells of anthers short, obtuse, mutic or aristate at the base, dehiscent by an oblong foramen; stigma simple or capitate, and in some species annulated with an elevated disc; capsule 4-celled, many seeded; seeds oval, compressed, smooth. (Don, Miller, iii.) The species, of which 112 are described, are all natives of the Cape of Good Hope. They are erect shrubs, with loose leaves and large showy flowers, which are crowded at the tops of the branches on every side, and form a spike-like inflorescence.

SYRINGOPORA. [MADREPHYLLICÆ.]

SYRINX. [SIPUNCULIDÆ.]

SYRNIUM, Savigny's name for a sub-genus of Owls. Ex. *Syrnium Aluco*, the well-known Brown Owl, Tawny Owl, or Ivy-Owl, or Wood-Owl, of these islands. [STRIGIDÆ.]

SYRPHIDÆ, a family of Dipterous Insects of the section *Brachystoma* of Macquart, the species of which are distinguished by their having the palpi inflated at the extremity, the fore part of the head often with a prominence, the labrum large, arched, and emarginated; the stylet of the antennæ is usually dorsal; the abdomen is most frequently depressed and elongated; the wings have one discoidal cell, three posterior cells, the first of which is closed, and the second extends along the posterior margin of the wing; sometimes there are some small terminal nervures; the anal cell is large, and a longitudinal nervure divides the discoidal cell, as well as the posterior.

The present family contains upwards of 40 genera, a great portion of which have representatives in this country. The species frequent flowers and woods; the larvæ of the species of *Syrphus* are in the form of an elongated cone; they fix themselves, &c., with a kind of glue, and feed exclusively on aphides. Some of the *Syrphidæ* inhabit the nests of the Humble-Bees (*Bombus*), and these so much resemble the species of *Bombi*, that they might at a first glance be mistaken for them. Other *Syrphidæ* live in the larva state in water and mud; and these larvæ are provided with a long slender tail, through the extremity of which they respire, it being raised to the surface of the water or mud for the purpose.

SYRRHAPTES. [TETRAONIDÆ.]

SYSTEM, SEXUAL, in Botany, is the name given to the method by which Linnaeus arranged the Vegetable Kingdom. In this system plants are divided into twenty-four classes, each of which is distinguished by the number and relative position of the stamens. The following are the classes:—

I. Flowers with Stamens and Pistils.

Class 1.	<i>Monandria</i>	flowers with	1 stamen.
2.	<i>Diandria</i>		2 stamens.
3.	<i>Triandria</i>		3 "
4.	<i>Tetrandria</i>		4 "
5.	<i>Pentandria</i>		5 "
6.	<i>Hexandria</i>		6 "
7.	<i>Heptandria</i>		7 "
8.	<i>Octandria</i>		8 "
9.	<i>Enneandria</i>		9 "

- Class 10. *Decandria* 10 stamens.
 11. *Dodecandria* 12-19 "
 12. *Icosandria* 20 or more stamens inserted into the calyx.
 13. *Polyandria* 20 or more stamens inserted on the receptacle.
 14. *Didynamia* 4 stamens; 2 long and 2 short.
 15. *Tetradynamia* 6 stamens; 4 long and 2 short. [CRUCIFERÆ.]
 16. *Monadelphia*; flowers with the filaments of the stamens united in one set.
 17. *Diadelphia*; flowers with the filaments of the stamens united in 2 sets. (In this class the flowers are papilionaceous.)
 18. *Polyadelphia*; flowers with the filaments of the stamens united in 3 or more sets.
 19. *Syngenesia*; flowers with the anthers of the stamens united. [COMPOSITÆ.]
 20. *Gynandria*; flowers with the stamens and pistils combined. [ORCHIDACEÆ.]

II. The Stamens and Pistils on different Flowers.

21. *Monœcia*; flowers with the stamens and pistils on the same individual.
 22. *Diœcia*; flowers with the stamens and pistils on different individuals.
 23. *Polygamia*; flowers perfect and unisexual, on the same or on different individuals.

III. Fructification concealed.

24. *Cryptogamia*. [ACROGENS.]

It will at once be seen that this system is exceedingly artificial, and that the great object of arrangement and classification in natural history is not attained by it. The effort of the naturalist in all systems should be to bring together those objects which most resemble each other, and to separate those which differ. A classification like the above, which takes only one organ or part of an organised being as a means of arrangement, is therefore certain to frustrate the great aim of the systematist. The only ground on which artificial classification such as the above can be tolerated is that of convenience in finding out the name of any particular object. It was undoubtedly this that led to the general adoption of the sexual system of Linnaeus by botanists. It is now however fast falling into disuse; and our catalogues of plants and manuals of indigenous Floras are written on the plan of the Natural System.

Linnaeus divided the above classes into orders in the same artificial way. The orders in the first thirteen classes were founded on the number of styles or stigmas in each flower. Thus, flowers having one style were placed in the order *Monogynia*, those with two in the order *Digynia*, with three in *Trigynia*, and so on. Thus the name of the orders are repeated in each of the thirteen classes. In the remaining classes however other points of structure are adopted. In *Didynamia* the orders are two, according as the fruit is 4-lobed or capsular. The first order is called *Gymnospermia*, and the second *Angiospermia*. These names were given by Linnaeus under the erroneous supposition that the 4-lobed ovary was a series of naked seeds.

The class *Tetradynamia* was divided into two orders, according to the form of the fruit. *Siliculosa* embracing the species with the fruit a silicle, and *Siliquosa* those with a silique.

In the classes *Monadelphia*, *Diadelphia*, and *Polyadelphia*, the number of the stamens was made the text of the orders, and these were named as the classes. Thus we have the order *Decandria*, class *Monadelphia*, and the order *Decandria*, class *Diadelphia*.

With regard to *Syngenesia* the following plan will afford the best idea of the nature of the orders:—

- Order 1. *Polygamia Equalis*.—Florets all hermaphrodites.
 Order 2. *Polygamia Superflua*.—Florets of the disc hermaphrodite, those of the ray pistilliferous and fertile.
 Order 3. *Polygamia Frustanea*.—Florets of the disc hermaphrodite, those of the ray neuter.
 Order 4. *Polygamia Necessaria*.—Florets of the disc staminiferous, those of the ray pistilliferous.
 Order 5. *Polygamia Segregata*.—Each floret having a separate involucre.
 Order 6. *Monogamia*.—Anthers united, flowers not compound.

This large class thus divided by Linnaeus forms the natural order *Compositæ*, and has been recently subdivided in a much less artificial manner than in the orders above given. [COMPOSITÆ.]

The class *Gynandria* was divided into orders by the number of the stamens. It includes the natural orders *Orchidaceæ* and *Aristolochiaceæ*.

The classes *Monœcia* and *Diœcia* are also formed into orders according to the number of stamens, and the orders are again named as preceding classes. Thus we have order *Diandria*, class *Diœcia*, &c.

The class *Polyœcia* has the following orders:—

- Order 1. *Monœcia*.—Hermaphrodite, staminiferous, and pistilliferous flowers on the same plant.

Order 2. *Diaccia*.—Flowers on two plants.

Order 3. *Tricaccia*.—Flowers on three plants.

The *Cryptogamia* were divided into the orders:—

<i>Filices</i>	Ferns.
<i>Musci</i>	Mosses.
<i>Hepaticæ</i>	Liverworts.
<i>Lichenes</i>	Lichens.
<i>Algæ</i>	Sea-Weeds.
<i>Fungi</i>	Mushrooms.

For the arrangement of the vegetable kingdom, according to the Natural System, see the articles EXOGENS; ENDOGENS; ACROGENS.

SYZYGIIUM, a large tropical genus of Plants belonging to the natural order *Myrtaceæ*, so named from *σύνυγος*, coupled, in consequence of the manner in which the branches and leaves are united together in pairs. The calyx-tube is obovate, with the limb nearly entire. Petals 4-5, forming a calyptra; stamens numerous, free; style

single; stigma simple; ovary 2-celled, ovules several in each cell. Berry 1-celled, 1- or few-seeded. Trees, or shrubs, of a highly ornamental appearance from their smooth shining leaves, which are opposite and entire.

Of the species, *S. Guineense*, a native of the coast of Guinea and Senegal, has been employed as a remedy in rheumatism. *S. paniculatum*, a native of the Isle of Bourbon, is there called Bois à Ecorce Blanche. *S. Jambolanum* is a native of the East Indies, and there most extensively diffused, being planted near villages in clumps of trees, chiefly on account of its fruit, which is sometimes called Java Plum by Europeans, but Jamoon by the natives. It is of a rich purplish colour, but of a subastringent sweetish taste, which is more agreeable to the native than to the European palate. The fruit is sometimes soaked for an hour in salt and water, when it makes an approach to the flavour of olives. The bark is astringent, and dyes of a brown colour; the wood is hard, close-grained, and durable, and therefore much employed.

T

TABERNÆMONTANA, a genus of Plants belonging to the natural order *Apocynaceæ*, found in the West Indies and South America, also in Australia, India, and other tropical parts of Asia. The genus is characterised by having monopetalous inferior flowers; corolla salver-shaped; stamens 5, included; anthers sagittate; ovaries 2; style filiform; stigma dilated at base, trifid. Seeds in a follicle, immersed in pulp. The flowers of many species are very sweet-scented, and the double-flowered variety of *T. coronaria* is a very ornamental shrub, and one of the most common in Indian gardens. The deep red pulp surrounding the seeds of this species appears capable of yielding a beautiful colour. The cream-like sap of *T. utilis*, the Milk-Tree, or Hya Hya of Demerara, is not only of an innoxious character, but said to be very nourishing. It affords a remarkable example of a tree of this suspected family yielding an article of food. Some of the other species are employed as medicines in the countries where they are indigenous. The sap of *T. persicariaefolia* is considered a poison in Mauritius. The wood is employed in turnery.

TABULAR SPAR. [WOLLASTONITE.]

TACCA, a genus of Plants belonging to the natural order *Taccaceæ*, placed near *Aroidaceæ* and *Aristolochiaceæ*, and resembling *Dioscoreaceæ*, in having radical tubers which abound in fæcula. The genus is named from the Malay name of one of the species, which are found in the hotter parts of India and in the South Sea Islands. The genus is characterised by having a 6-partite calyx, with a 6-partite corolla, and 6 stamens which are inserted in the calyx; styles 3; stigmas stellate. Berry dry, hexangular, many-seeded. The plants have perennial tubers, with a short compressed rhizome, from which proceed the stalked and the so-called radical leaves and herbaceous scapes. The plants of this family are possessed of some acidity both in their tubers and in their herbaceous parts, but the roots lose some of this quality by culture, at the same time that they become larger. Those of *T. pinnatifida*, the best-known species, and a native of the Malayan Peninsula, the Moluccas, Madagascar, and Australia, are roundish, red, the size of a man's fist, extremely bitter, and acid. The tubers of this plant, and also those of *T. dubia* and *T. montana*, are rasped and macerated for four or five days in water; a white highly nutritious fæcula like arrow-root is then separated, and, like sago, is employed as an article of diet by the inhabitants of the Malayan Peninsula and the Moluccas. In Tahiti and some of the Society Islands they make cakes of the tubers of *T. pinnatifida*, which are the Tacca Yony of some navigators. They form an article of diet in China and Cochinchina, and also in Travancore, in India, where, according to Dr. Ainslie, they attain a large size, and the natives eat them with some acid to subdue their acrimony. (Royle's 'Illustr.', p. 378.) The petioles and stalks boiled for some time are also used as articles of diet in China and Cochinchina. In Tahiti the plant is called Tya: its fæcula is largely prepared, and is sometimes preferred to that of arrow-root by the English, to whom it is sold under that name by the native converts at the missionary station, and exported to London. It is also sometimes called Tahiti Salep. This plant must not be confounded with the *Arum macrorrhizum*, the tuberous root-stalk of which is also edible, and when prepared is called Taka, which similarity in name and in uses has frequently caused confusion, and the mistaking of one plant for the other. In Singapore *T. cristata* is called Water-Lily.

TACCA'CEÆ, a small natural order of Endogenous Plants belonging to the Epigynous group. There are but two genera belonging to this order, *Tacca* and *Ataccia*. The species are large perennial herbaceous plants, with a tuberous root, a short stem bearing scapes, and having exstipulate radical pedatifid pinnatifid rarely entire leaves, with curved parallel veins. The flowers, which are placed on the top of a single scape, are in umbels, and are united; the tube of the perianth is superior, and united to the germen; limb petaloid, equal or unequal, persistent; stamens 6; filaments dilated; ovary composed of 3 connected carpels, with 5 parietal polyspermous placentæ; styles 3, con-

nate. The fruit baccate, with seeds lunate, striated, and the embryo situated on the outside of fleshy albumen.

The species are found in the hotter parts of India, in the South Sea Islands, also in tropical Africa. [TACCA.]

TACHYDROMUS. [ZONURIDÆ.]

TACHYGLOSSUS, Illiger's name for the *Echidna*. [ECHIDNA.]

TACHYLITE, a Mineral which resembles Obsidian, and has also been supposed to be similar to Isopyre. It occurs in plates and massive. No cleavage. Fracture small, conchoidal. Hardness 6.5. Translucent, opaque. Lustre vitreous, vitreo-resinous. Colour brownish and greenish-black. It is found in small masses at Säsbühl, near Göttingen, in basalt and wacke.

TACHYPETES. [PELECANIDÆ.]

TACHYPHONUS. [FRINGILLIDÆ.]

TACHYTES. [LARIDÆ.]

TADORNA (Leach), a genus of Birds belonging to the family *Anatidæ*, having the bill very much flattened towards the extremity, and elevated into a protuberance or projecting boss at its base. [DUCKS.]

Head and Foot of *Tadorna*.

TADPOLE. [AMPHIBIA.]

TADPOLE-FISH. [RANIDÆ.]

TÆNIA. [ENTOZOA.]

TÆNIOIDES, a family of Acanthopterygious Fishes nearly allied to the Mackerela. The species comprising it are all long flattened fishes, with very small scales. The following are among the principal genera.

Lepidopus, tænioid fishes with elongated snouts, a wide gape, projecting under jaw, and strong sharp cutting teeth. The ventral fins are reduced to small scaly plates. The tail is well formed. The *L. argyreus* or Scabbard-Fish is an example. It is of a bright silver-colour, and attains a length of six feet. It is one of the rarest of British fishes.

Trichiurus resembles the last genus in the character of the head, but has neither ventral nor caudal fins, the tail being represented by a long slender compressed filament. The *T. lepturus* of Linneus, an inhabitant of the Atlantic, attains a length of more than 12 feet, and resembles a beautiful silver ribbon.

The genus *Lophotes* of Giorna has a short head with a bony crest bearing a long and stout spine. The caudal fin is distinct, but very small. The *Stylephorus* of Shaw is allied to *Gymnetrus*, but has the tail prolonged into a slender filament, exceeding the length of the body. [GYMNETRUS; CEPOLA.]

TÆNIOPTERA. [TÆNIOPTERINÆ.]

TÆNIOPTERINÆ, Mr. G. R. Gray's name for his second family of *Muscipidæ*. [MUSCIPIDÆ.]

TÆNIOPTERIS, a Fossil Fern from the Oolite.

TALAUMA. [MAONOLIACÆ.]

TALC, a Mineral which occurs crystallised and massive, and it is probable that some distinct species of minerals have been so called. Primary form of the crystal a rhomboid, but it usually occurs in the secondary form of hexagonal laminae, and sometimes in long prisms.

Cleavage distinct, perpendicular to the axis. It is easily separable into thin plates, which are flexihle, but not elastic. It is easily scraped with a knife, and the powder is unctuous to the touch. Colour white, green, grayish, and blackish-green and red. Becomes negatively electrical by friction. Lustre pearly. Transparent, translucent, opaque. Specific gravity 2.713.

Crystallised Talc is mostly white, or of a light-green colour; is met with in serpentine rocks in small quantity, with carbonate of lime, actinolite, steatite, and massive talc, &c. It is found in the mountains of Salzburg and the Tyrol: it occurs in many other parts of the world, as in Cornwall, in Kynan's Cove, where a bed of it underlies serpentine. It also occurs in Scotland, in Glen Tilt, Perthshire; and in Saxony, Silesia, and Piedmont, &c.

The massive varieties of Talc are less flexible than the crystallised: they are principally of an apple-green colour, and sometimes of a radiated structure. It is met with in considerable quantity in beds in micaceous schists, gneiss, and serpentine.

Some of the varieties of Talc are infusible; others become white, and yield a small button of enamel with horax.

Indurated Talc is massive, of a greenish-gray colour; the structure is schistose and curved: it is of a shining and sometimes of a pearly lustre, and somewhat translucent. It is soft and rather unctuous to the touch. Its specific gravity is 2.9.

It occurs in primitive mountains in clay-slate and serpentine, in several countries on the continent of Europe; in Britain, in Perthshire and Banffshire in Scotland, and in the Shetland Islands. According to Vauquelin, Lamellar Talc consists of—

Silica	62.0
Magnesia	27.0
Alumina	1.8
Oxide of Iron	3.2
Water	6.0
	—100

Steatite, Chlorite, Potstone, and other magnesian minerals are nearly allied to Mica, and they are by some mineralogists considered as varieties of the same substance. [STEATITE; CHLORITE.]

TALEGALLA, a genus of Birds belonging to the *Megapodiinae*, which Mr. G. R. Gray makes the third and last sub-family of his *Palamedeidae*. [PALAMEDEA.]

The *Megapodiinae* comprise the following genera:—*Talegalla*, Less. (*Alectura*, Lath.; *Talegallus*, Less.; *Numida*, James; *Catheturus*, Sw.); *Megapodius*, Quoy et Gaim.; *Mesites* (?), J. Geoffr.; *Menura*, Shaw (*Parkinsonius*, Bechst.; *Megapodius*, Wagl.); *Alethelia*, Less. (nec Swaina). [CRACIDÆ.]

Talegalla has the bill very robust, very thick, one-third of the length of the head compressed above, with the upper mandible convex; nostrils basal, lateral, oval-oblong, pierced in a large membrane; lower mandible less high but wider than the upper, nearly straight below, with smooth edges, the branches widened at the base, and that width filled up by a feathered membrane; cheeks entirely naked; head and neck furnished with feathers with simple barbules. Wings rounded, moderate, the first quill very short, the second rather longer, the third longest of all, the fourth and fifth diminishing in length after the third. Tail rather long, rounded; tarsi rather robust, moderately long, furnished with large scutella in front; toes rather long, the middle longest, the external shortest; the three front toes furnished at their origin with a membranous border, which is widest between the external and middle toes; claws convex, flattened below, slightly curved, and moderately robust; the hind-toe long, resting entirely on the ground, and furnished with an equally robust claw. (Lesson.)

Head and Foot of *Talegalla*. (Gould.)

T. Lathamii. Latham, in his 'General History of Birds' (vol. i.), described and figured this bird under the name of the New Holland Vulture; but, correcting his error, he in the tenth volume, placed it among the Gallinaceous Birds, with the generic name of *Alectura*, which had been previously employed to designate a group of Fly-catchers.

Mr. Lesson places the genus at the end of the *Phasianidae*.

Mr. Swainson places it amongst the *Vulturidae*: yet it is no bird of prey at all.

Mr. Gould, to whom we are indebted for a full and satisfactory

account of the habits of this extraordinary bird, says:—"After all the facts that have been stated, I trust it will be evident that its natural situation is among the *Rasores*, and that it forms one of a great family of birds peculiar to Australia and the Indian Islands, of which *Megapodius* forms a part; and in confirmation of this view I may add, that the sternum has the two deep emarginations so truly characteristic of the *Gallinaceae*; at all events it is in no way allied to the *Vulturidae*, and is nearly as far removed from *Menura*." It seems to us that *Talegalla Lathamii* may be considered, in a degree, as the representative of the Turkey in Australia.

The adult male of this bird has the whole of the upper surface, wings, and tail, blackish-brown; the feathers of the under surface blackish-brown at the base, becoming silvery-gray at the tip; skin of the head and neck deep pink-red, thinly sprinkled with short hair-like blackish-brown feathers; wattle bright yellow, tinged with red where it unites with the red of the neck; bill black; irides and feet brown.

Female about a fourth less than the male in size, but so closely the same in colour as to render a separate description unnecessary. She also possesses the wattle, but not to so great an extent. (Gould.)

It is about the size of a turkey.

Wattle Talegalla (*Talegalla Lathamii*). (Gould.)

Mr. Gould gives the following synonyms:—New Holland Vulture, Latham; genus *Alectura*, Latham; *Alectura Lathamii*, J. E. Gray; Australian Vulture, *Catheturus Australis*, Swainson; *Meleagris Lindsargii*, Jameson; Brush Turkey of the colonists; Weelah of the aborigines of the Namoi.

Mr. Gould describes *Talegalla Lathamii*, or the Wattle Talegalla, as a gregarious bird, generally moving about in small companies, much after the manner of the *Gallinaceae*, and, like some species of that tribe, as very shy and distrustful. When it is disturbed, he states that it readily eludes pursuit by the facility with which it runs through the tangled brush. If hard pressed, or where rushed upon by their great enemy, the native dog, the whole company spring upon the lowermost bough of some neighbouring tree, and, by a succession of leaps from branch to branch, ascend to the top, and either perch there or fly off to another part of the brush. They resort also to the branches of trees as a shelter from the sun in the middle of the day, a habit which Mr. Gould notices as greatly tending to their destruction; for the sportsman is enabled to take a sure aim, and the birds, like the ruffed grouse of America, will allow a succession of shots to be fired till they are all brought down.

But the most remarkable circumstance connected with the economy of this bird is its nidification, for it does not hatch its eggs by incubation. It collects together a great heap of decaying vegetables, as the place of deposit of its eggs, thus making a hot-bed arising from the decomposition of the collected matter, by the heat of which the young are hatched. Mr. Gould describes this heap as the result of several weeks' collection by the birds previous to the period of laying, as varying in quantity from two to four cart-loads, and as of a perfectly pyramidal form. This mound, he states, is not the work of a single pair of birds, but is the result of the united labour of many: the same site appeared to Mr. Gould to be resorted to for several years in succession, from the great size and entire decomposition of the lower part, the birds adding a fresh supply of materials on each occasion previous to laying.

"The mode," says Mr. Gould in continuation, "in which the materials composing these mounds are accumulated is equally singular, the bird never using its bill, but always grasping a quantity in its foot, throwing it backwards to one common centre, and thus clearing the surface of the ground for a considerable distance so completely, that scarcely a leaf or a blade of grass is left. The heap being accumulated, and time allowed for a sufficient heat to be engendered, the eggs are deposited, not side by side, as is ordinarily the case, but planted at the distance of nine or twelve inches from each other, and

buried at nearly an arm's depth, perfectly upright, with the large end upwards: they are covered up as they are laid, and allowed to remain until hatched. I have been credibly informed, both by natives and settlers living near their haunts, that it is not an unusual event to obtain nearly a bushel of eggs at one time from a single heap; and as they are delicious eating, they are eagerly sought after. Some of the natives state that the females are constantly in the neighbourhood of the heap about the time the young are likely to be hatched, and frequently uncover and cover them up again, apparently for the purpose of assisting those that may have appeared; while others have informed me that the eggs are merely deposited, and the young allowed to force their way unassisted. In all probability, as nature has adopted this mode of reproduction, she has also furnished the tender birds with the power of sustaining themselves from the earliest period; and the great size of the egg would equally lead to this conclusion, since in so large a space it is reasonable to suppose that the bird would be much more developed than is usually found in eggs of smaller dimensions. In further confirmation of this point, I may add, that in searching for eggs in one of the mounds, I discovered the remains of a young bird, apparently just excluded from the shell, and which was clothed with feathers, not with down, as is usually the case: it is to be hoped that those who are resident in Australia, in situations favourable for investigating the subject, will direct their attention to the further elucidation of these interesting points. The upright position of the eggs tends to strengthen the opinion that they are never disturbed after being deposited, as it is well known that the eggs of birds which are placed horizontally are frequently turned during incubation. Although unfortunately I was almost too late for the breeding-season, I nevertheless saw several of the heaps, both in the interior and at Illawarra: in every instance they were placed in the most retired and shady glens, and on the slope of a hill, the part above the nest being scratched clean, while all below remained untouched, as if the birds had found it more easy to convey the materials down than to throw them up. In one instance only was I fortunate enough to find a perfect egg, although the shells of many from which the young had been excluded were placed in the manner I have described. At Illawarra they were rather deposited in the light vegetable mould than among the leaves, which formed a considerable heap above them. The eggs are perfectly white, of a long oval form, three inches and three quarters long by two inches and a half in diameter." ('Birds of Australia.')

The same author relates that these birds, while stalking about the wood, frequently utter a loud clucking noise; and, in various parts of the bush, he observed depressions in the earth, which the natives informed him were made by the birds in dusting themselves. The stomach is stated by Mr. Gould to be extremely muscular; and he found the crop of one which he dissected filled with seeds, berries, and a few insects.

The composure with which these birds sit to be shot at, as above noticed, must, as Mr. Gould observes, lead to an early extinction of the race; an event, he remarks, much to be regretted, since, independently of its being an interesting bird for the aviary, its flesh is extremely delicate, tender, and juicy. There is no doubt that this species may be domesticated, and it would make a noble addition to those foreign denizens of the poultry-yard which enrich our homesteads and tables. Living specimens are now (1855) existing in the Gardens of the Zoological Society, Regent's Park.

M. Lesson describes the species from New Guinea, which serves as the type of his genus *Talegalla Cuvieri*, figured in the 'Zoologie de la Coquille,' as entirely black, of the size of a common small hen, and recalling to the observer some of the forms of the *Porphyrio*nes. [RALLIDE.]

We subjoin descriptions of the genus *Leipoa*, and a species of *Megapodius*, which deposit their eggs in mounds as done by *Talegalla*.

Leipoa (Gould).—Bill nearly as long as the head, slender, tumescent at the base, the edges undulated and incurved at the apex; the nostrils ample, oblong, covered with an operculum, and placed in a central hollow; head suberected. Wings ample, rounded, concave; fifth primary quill the longest; the tertiaries nearly as long as the primaries. Tail rounded, tail-feathers 14. Tarsi moderate, robust, covered with scuta anteriorly, and posteriorly with scales, which are rounded and unequal. Toes rather short; lateral toes nearly equal. (Gould.)

Head and Foot of *Leipoa*.

L. ocellata, Ocellated Leipoa (Gould). In size this beautiful bird is inferior to *T. lathamii*, and it is more slender and more elegantly formed. According to Mr. Gould, it is the Ngow of the aborigines of

the lowland; Ngow-oo of the mountain districts of Western Australia; and Native Pheasant of the colonists of Western Australia.

Mr. Gould, in his 'Birds of Australia,' gives an account of this bird. It is described as a ground-bird, never taking to a tree except when closely hunted: when hard pursued, it will frequently run its head into a hush, and is then easily taken. Its food generally consists of seeds and berries. The note is mournful, very much like that of a pigeon, but with a more inward tone. The eggs are deposited in a mound of sand, the formation of which is the work of both sexes. According to the natives, the birds scratch up the sand for many yards around, forming a mound about three feet in height, the inside of which is constructed of alternate layers of dried leaves, grasses, &c., among which twelve eggs and upwards are deposited, and are covered up by the birds as they are laid; or, as the natives express it, "the countenances of the eggs are never visible." Upon these eggs the bird never sits, but when she has laid out her lay, as the henwires say, the whole are covered up, when the mound of sand resembles an ant's nest. The eggs, which are white, very slightly tinged with red, and about the size of a common fowl's egg, are hatched by the heat of the sun's rays, the vegetable lining retaining sufficient warmth during the night: they are deposited in layers, no two eggs being suffered to lie without a division. This bird is a native of Western Australia.

Ocellated Leipoa (*Leipoa ocellata*). (Gould.)

The species of *Megapodius* [CRACIDÆ] which has the habit of these birds, is *M. tumulus*. It is thus described by Mr. Gould:—Head and crest very deep cinnamon-brown; back of the neck and all the under surface very dark gray; back and wings cinnamon-brown; upper and under tail-coverts dark chestnut-brown; tail blackish-brown; irides generally dark-brown, but in some specimens light reddish-brown; bill reddish-brown, with yellow edges; tarsi and feet bright orange, the scales on the front of the tarsi from the fourth downwards, and the scales of the toes, dark reddish-brown. Size about that of a common fowl.

This is the Ooregoorga of the aborigines of the Cobourge Peninsula; the Jungle-Fowl of the colonists of Port Essington.

Head and Foot of *Megapodius*. (Gould.)

Mr. Gould gives a highly interesting account of the habits of this bird. He states that on Mr. Gilbert's arrival at Port Essington, his attention was attracted to numerous great mounds of earth which were pointed out to him by some of the residents as being the tumuli of the aborigines. The natives, on the other hand, assured him that they were formed by the Jungle-Fowl for the purpose of hatching its eggs. But this last statement appeared so extraordinary, and so much at variance with the general habits of birds, that no one in the settlement believed them, and the great size of the eggs brought in by them as the produce of this bird strengthened the doubt of the veracity of their information. Mr. Gilbert however, knowing the habits of *Leipoa*, took with him an intelligent native, and proceeded about the middle of November to Knocker's Bay, a part of Port Essington harbour comparatively but little known, and where he had been informed a number of these birds were to be seen. He landed beside a thicket,

and had not advanced far from the shore when he came to a mound of sand and shells, with a slight mixture of black soil, the base resting on a sandy beach, only a few feet above high-water mark; it was enveloped in the large yellow-blossomed *Hibiscus*, was of a conical form, twenty feet in circumference at the base, and about five feet high. On asking the native what it was, he replied 'Oregoorā Rambal' (Jungle-Fowl's house or nest). Mr. Gilbert scrambled up the side of it, and found a young bird in a hole about two feet deep; the nestling, apparently only a few days old, was lying on a few dry withered leaves.

Mr. Gilbert afterwards secured several eggs from the nests. On one occasion, after an hour's excessive labour, Mr. Gilbert obtained an egg from the depth of about five feet. It was in a perpendicular position. The holes in this mound (which was 15 feet high and 60 feet in circumference at the base, and, like the majority of those that he had seen, so enveloped in thickly-foliaged trees as to preclude the possibility of the sun's rays reaching any part of it) commenced at the outer edge of the summit, and ran down obliquely towards the centre: their direction, therefore, Mr. Gilbert observes, is not uniform. The mound was quite warm to the hands.

How the young effect their escape does not appear: some natives told Mr. Gilbert that the nestlings effected their escape unaided; but others said that the old birds, at the proper time, scratched down and released them. The natives say that only a single pair of birds are ever found at a mound at a time.

Mound-Raising Megapode (*Megapodius tunulus*), with nest in the distance. (Gould.)

TALIPAT-, or TALIPOT-PALM. [CORYPHA.]

TALLIERA. [CORYPHA.]

TALLOW, a name applied to various forms of solid oils and fat.

[FAT; ADIPOSE TISSUE; OIL.]

TALLOW, MINERAL or MOUNTAIN. [HATCHETINE.]

TALLOW-TREE. [STILLINGIA.]

TALPA. [TALPIDÆ.]

TALPASO'REX. [SORECIDÆ.]

TALPIDÆ, a family of Animals belonging to the order *Insectivora*, and including the Moles.

The genus *Talpa* of Linnæus, as it stands in the 12th edition of the 'Systema Naturæ,' between the genera *Didelphis* and *Sorex*, comprises two species only, *Talpa Europæa*, the Common Mole, and *T. Asiatica*. [CHRYSOCHLORIS.]

Cuvier places the Moles, confining them to the genus *Talpa*, between *Sorex* [SORECIDÆ] and *Condylura*.

Mr. Swainson places the genus *Talpa* between *Chrysochloris* and *Centenex*.

and working of the muzzle. The part which extends from the internal side of the jaws terminates in three points, the one in the

Skull of Mole.

middle larger and more distant from the external edge than the other two. The very short arm attached by means of a long bladebone, and sustained by a vigorous clavicle, carries an extremely wide hand, the palm of which is always turned outwards or backwards. No known living form has the compressed phalangeal bones seen in *Glyptodon* except the Mole. [GLYPTODON.] The second phalanx of the anterior digits or fingers of the Mole is the only known living analogue of the similar bone in the hind foot of *Glyptodon*. The sternum, like that of the Birds and Bats, has an elevation or crest affording room for the large pectoral muscles. The pelvis and hinder extremities are comparatively feeble. The bones of the pubis are not joined.

This bony framework is set in motion by very powerful muscles. Those of the anterior extremities, the chest, and the neck are most vigorous, and in the cervical ligament a peculiar bone is even formed. The wide hand, which is the great instrument of action, and performs the offices of a pickaxe and shovel, is sharp-edged on its lower margin, and, when clothed with the integuments, the fingers are hardly distinguishable, but the terminating claws project long, strong, flat, and trenchant.

The muzzle of the Mole is evidently a delicate organ of touch, and that sense is considerably developed in the large and broad hands and feet. Neither is the tail without a considerable share of sensation, to give notice to the animal of the approach of any attack from behind. The gustatory and olfactory nerves, especially the latter, appear to be very sensitive.

The eye is so bidden in the fur, that its very existence was for a long time denied. It appears to be designed for operating only as a warning to the animal on its emerging into the light; and indeed more acute vision would only have been an incumbrance.

The sense of hearing is very highly developed, and the tympanum very large, though there is no external ear, or rather, no projecting concha.

There is nothing that calls for any particular notice in the digestive system of the Mole. The alimentary canal is short, simple, without a cæcum. The voracity of the Mole corresponds with the activity and rapidity of its digestive powers. An interesting series of preparations illustrative of the anatomy of the Mole, will be found in the Museum of the Royal College of Surgeons, London.

The family *Talpidae* is thus characterised:—Head long, narrow, somewhat depressed; nose much prolonged, pointed flexible; eyes very minute; ears hidden; feet plantigrade; anterior limbs largely developed.

Talpa.—Body stout and thick, furry; head elongated, pointed; muzzle cartilaginous, strengthened by the snout-bone; eyes very small; no external ears; anterior feet short and wide, with five united toes armed with trenchant nails proper for digging; posterior feet with five toes also, but weak. Tail short.

Dental Formula:—Incisors, $\frac{6}{8}$; Canines, $\frac{1-1}{0-0}$; Molars, $\frac{7-7}{7-7} = 14$.

Skeleton of Mole. (De Blainville.) The nuchal bone and accessory carpal sabre-shaped bone are here shown.

The organisation of these animals is very peculiar. The cranium is elongated and pointed, and there is a peculiar bone for the support

T. Europæa, the Common Mole. This well-known animal, so familiar to all that it would be a needless waste of space to describe

Teeth of Mole, considerably enlarged. (F. Cuvier.)

it, is *La Taupe* of the French, *Talpa* of the Romans and Italians, *Topo* of the Spanish, *Toupeira* of the Portuguese, *Maulwurf* of the Germans, *Mol* of the Dutch, *Mulvad* and *Snrk* of the Swedes, *Muld-varp* of the Danes; *Mole*, *Mole-Warp*, *Moldwarp*, and *Want* of the English; and *Gwadd* and *Twreh-Dacur* of the Welsh.

"A subterranean life," says Pennant, speaking of the Mole, "being allotted to it, the seeming defects of several of its parts vanish; which, instead of appearing maimed or unfinished, exhibit a most striking proof of the fitness of their contrivance. The breadth, strength, and shortness of the fore feet, which are inclined sideways, answer the use as well as the form of hands, to scoop out the earth, to form its habitation, or to pursue its prey. Had they been longer, the falling in of the earth would have prevented the quick repetition of its strokes in working, or have impeded its course: the oblique position of the fore feet has also this advantage, that it flings all the loose soil behind the animal.

"The form of the body is not less admirably contrived for its way of life: the fore part is thick and very muscular, giving great strength to the action of the fore part, enabling it to dig its way with great force and rapidity, either to pursue its prey or elude the search of the most active enemy. The form of its hind parts, which are small and taper, enables it to pass with great facility through the earth that the fore feet had flung behind; for had each part of the body been of equal thickness, its flight would have been impeded and its security precarious.

"The skin is most excessively compact, and so tough as not to be cut but by a very sharp knife; the hair is very short and close-set, and softer than the finest silk; the usual colour is black, not but that there are instances of these animals being spotted, and a cream-coloured breed is sometimes found in my lands near Downing.

"The smallness of the eyes (which gave occasion to the ancients to deny it the sense of sight) is to this animal a peculiar happiness; a small degree of vision is sufficient for an animal ever destined to live underground; had these organs been larger, they would have been perpetually liable to injuries by the earth falling into them; but nature, to prevent that inconvenience, hath not only made them very small, but also covered them very closely with fur. Anatomists mention (besides these) a third very wonderful contrivance for their security, and inform us that each eye is furnished with a certain muscle, by which the animal has the power of withdrawing or exerting them, according to its exigencies.

"To make amends for the dimness of its sight, the Mole is amply recompensed by the great perfection of two other senses, those of hearing and of smelling: the first gives it notice of the most distant approach of danger; the other, which is equally exquisite, directs it in the midst of darkness to its food: the nose also, being very long and slender, is well formed for thrusting into small holes in search of the worms and insects that inhabit them. These gifts may with reason be said to compensate the defect of sight, as they supply in this animal all its wants and all the purposes of that sense.

"It is supposed that the verdant circles so often seen in grass-grounds, called by country-people fairy-rings, are owing to the operations of these animals, who, at certain seasons perform their burrowings by circumgyrations, which, loosening the soil, give the surface a greater fertility and rankness of grass than the other parts within or without the ring.

"The Mole breeds in the spring, and brings four or five young at a time: it makes its nest of moss, and that always under the largest hillock, a little below the surface of the ground. It is observed to be most active, and to cast up most earth, immediately before rain, and

in the winter before a thaw, because at those times the worms and insects begin to be in motion and approach the surface: on the contrary, in very dry weather this animal seldom or never forms any hillocks, as it penetrates deep after its prey, which at such seasons retires far into the ground. During summer it runs in search of snails and worms in the night time among the grass, which makes it the prey of owls. The Mole shows great art in skinning a worm, which it always does before it eats it; stripping the skin from end to end and squeezing out the contents of the body."

Le Court, a French writer, has given the most complete account of the habitation of the Mole:—The principal point is the habitation, or, as it has been termed, the fortress; and is constructed under a considerable hillock raised in some secure place, often at the root of a tree, under a bank, or any shelter that offers protection. The fortress is domed by a cement, so to speak, of earth which has been beaten and compressed by the architect into a compact and solid state. Within, a circular gallery is formed at the base, and communicates with a smaller upper gallery by means of five passages, which are nearly at equal distances. Within the lower and under the upper of these galleries is the chamber, or dormitory, which has access to the upper gallery by three similar passages. From this habitation, we should here observe, the high road by which the proprietor reaches the opposite end of the encampment extends, and the various galleries or excavations open into this road, which the mole is continually carrying out and extending in its search for food, and which has been termed its hunting-ground. But to return to the chamber. From it another road extends, the direction of which is downwards at first, and that for several inches, when it again rises to open into the high road of the territory. Some eight or nine other passages open out from the external circular gallery, but the orifices of these never come opposite to the passages which connect the external gallery with the internal and upper gallery. The extent of these passages is greater or less according to circumstances, and they each return by an irregular and semicircular route, opening at various distances from the habitation into the high road, which differs considerably from all the other passages and excavations, both in construction and with regard to the use to which it is applied. From the habitation this road is carried out nearly in a straight line, and forms the main passage of communication between the habitation, the different portions of the encampment, and the alleys leading to the hunting-ground which open into it on each side. In diameter it exceeds the body of a mole, but its size will not admit of two moles passing each other. The walls, from the reiterated pressure of the mole's sides against them, become smooth and compact, and its course is remarkable for the comparative absence of mole-hills, which are frequent in connection with the alleys and quarries, as they have been termed, in constructing which the earth is removed out of the way to the surface. Sometimes a mole will lay out a second or even a third road in order to the extension of its operations. Sometimes several individuals use one road in common, though they never trespass on each other's hunting-grounds. In the event of common usage, if two moles should happen to meet, one must retreat into the nearest alley, unless both should be pugnacious; in which case the weakest is often slain. In forming this tunnel the mole's instinct supplies the place of science, for he drives it at a greater or less depth, according to the quality of the soil, or concurrent circumstances. When there is nothing superincumbent threatening a disturbance of its security, it is often excavated at a depth of some four or five inches; but if it is carried under a road or a stream, a foot and a half of earth, sometimes more, is left above it. Thus does the little animal carry on the subterranean works necessary for his support, travelling, and comfort; and his tunnels never fall in.

Habitation or Fortress of Mole.

The alleys opening out from the sides of the high road have generally a somewhat downward inclination from their commencement

towards their end. It has been observed that when, on opening one of these alleys, a plentiful supply of food is found, the mole proceeds to work out branch-alleys from its termination, upheaving new mole-hills as it advances in quest of prey. Should however the soil be barren of the means of existence, the animal commences another alley at a different part of the high road. The quality and humidity of the soil, which regulate the abundance of earth-worms, determine the greater or less depth of the alleys.

The main road being the highway of communication to its different hunting-grounds, it is necessarily passed through regularly in the course of the day, and it is in this road that the mole-catcher sets his traps or practices his devices to intercept the animal between its habitation and the alley where it is carrying on its labours. Some mole-catchers will tell you that the hours when the moles move are nine and four, and others, that near the coast their movements are influenced by the tides; to which statements the reader is at liberty to give as much credence as he chooses. Besides the various traps which are set for them, there is, or very lately was, a man who travelled the country with a dog and destroyed them without any trap at all, by the following process:—Taking his station at the proper time and place, attended by his dog, and armed with a spear or spud, he waits till the dog indicates the presence of the mole, and then spears or spuds the animal out as it moves in its run. Pointers will stop at moles as steadily as at game when the latter are straying on the surface.

Besides the excavations already noticed, the moles pursue another mode of hunting in light loose soils, newly sown, when gentle rains have led the earth-worms towards the surface, along which they follow the worms up, rapidly digging a shallow trench in the superficial layer of the soil. The female, when with young, is said to be principally addicted to this easier method of subsistence.

We must not omit to notice the provision of this animal to secure a supply of water, for its voracity makes it a great drinker. If a pond or ditch be at hand in those cases where many moles use the same common highway, a run is always made to the reservoir: when it is too distant, the animal sinks little holes in the shape of deep perpendicular shafts, which hold water. These wells have sometimes been seen brim-full.

During the season of love, at which time bloody battles are fought between the males, the male pursues the female with ardour through numerous divaricating superficial runs wrought out with great rapidity, termed 'coupling runs' and 'running angles' by our mole-catchers, and 'traces d'amour' by the French. The young are generally produced in April, but have been found from that month to August. From four to five is the general number, though from three to six have been recorded, and in one case seven in one nest. The nest is distinct, usually distant from the habitation, and not always crowned with a hillock; but when a hillock exists it is much larger than an ordinary mole-hill. It is constructed by enlarging and excavating the point where three or four passages intersect each other; and the head of the nest is formed of a mass of young grass, root-fibres, and herbage. In one case, Geoffroy St. Hilaire and Le Court counted 204 young wheat-blades.

Heavy charges have been brought against the Mole by agriculturists and horticulturists, and the more grave accusation of being ancillary to the destruction of dykes has been in some instances proved upon it. Mr. Bell, in his interesting 'History of British Quadrupeds,' sums up the evidence against it and in its favour. On the whole there appears to be no ground for the war of extermination which is carried on against it.

Moies are good swimmers, and their hite is very sharp. When their blood is up, their ferocity is great, and they keep their hold like a bull-dog.

The Common Mole is found throughout the greater part of the continent of Europe and its larger islands. In Greece it is said to be comparatively rare. We are overrun with it in most parts of England and Wales, but it does not appear to have been found in the northern extremity of Scotland, though it is frequent enough in the south. There is no record of its having been seen in the Orkney Isles, Zetland, or Ireland.

Fossil remains of the Mole have been found in the bone-caverns; as, for example, in the cave at Köstritz and at Paviland. (Buckland, 'Reliquiæ Diluvianæ.'). They have also been found in the bone-caverns in Belgium (Schmerling).

Bones of Moies have been obtained from the brown clay of Norfolk. TAMANDUA. [ANT-EATER.]

TAMARICA/CEÆ, *Tamarisks*, a small natural order of Plants, belonging to the syncarpous group of Polypetalous Exogens. The species are either shrubs or herbs, having rod-like branches, with alternate entire leaves, resembling scales; the flowers are in dense spikes or racemes. The calyx is 4-5-parted, persistent; the petals inserted into the calyx, both with imbricate aestivation; stamens hypogynous, distinct or united, equal in number with the petals or twice as many; ovary superior, with a short style and 3 stigmas; fruit a capsule, 3-valved, 1-celled, with numerous seeds, which are comose; embryo straight with an inferior radicle.

The species are found only in the Old World; the greatest number being met with in the basin of the Mediterranean.

The plants of this order are innocuous, and all are more or less astringent; and their ashes after burning are remarkable for possessing a large quantity of sulphate of soda. *Myricaria Germanica* is recommended as a diuretic. [TAMARIX.]

Tamarix Germanica.

a, cutting, showing the straight branches and scale-like leaves; b, single flower; c, flower with calyx and corolla removed, showing monadelphous stamens; d, capsule with comose seeds escaping.

TAMARIN. [MIDAS.]

TAMARIND. [TAMARINDUS.]

TAMARINDUS, a genus of Plants belonging to the Rectembryous division of the natural order *Leguminosæ*. It possesses the following characters:—Calyx cleft, tubular at the base, the three upper lobes reflexed, the two lower ones joined together, but usually indented at the apex; petals 3, alternate with the three upper lobes of the calyx, the middle one cucullate and the lateral ones ovate; the stamens are 9 or 10 in number, two or three of which are longer than the others, united at the base, and bearing anthers, whilst the remainder are sterile; the fruit is a legume seated on a pedicel, 1-celled, compressed, with from 3 to 6 seeds, and the valves filled with pulp between the endocarp and epicarp, their inner and outer lining; the seeds are ovato-quadrate in form, possessing cotyledons unequal at the base.

There are only two species belonging to this genus, both of which are trees with abruptly pinnate leaves, bearing many pairs of small leaflets and racemes of flowers.

T. Indica, the East Indian Tamarind, was the earliest known species, for a knowledge of which, in Europe, we are indebted to the Arabians. It is distinguished by its elongated legumes, which are six times or more longer than they are broad. It is a native of various districts in the East Indies and also of the tropical parts of Africa. It forms a handsome tree with spreading branches, bearing leaves of a light colour and flowers with a straw-coloured calyx and yellow petals, streaked with red; the filaments of the stamens are purple and the anthers brown. The timber of this tree is very firm, hard, and heavy, and is applied to many useful purposes in building.

A second species is the *T. occidentalis*, the West Indian Tamarind, which is distinguished from the other by possessing short legumes not more than three times longer than they are broad. It is a native of South America and the West Indian Islands, forming also a large spreading tree, with yellowish flowers streaked with red, and purplish stamens.

TAMARIX, the name of a genus of Plants, the type of the natural order *Tamaricaceæ*. It has a 4- or 5-parted calyx; 4 or 5 petals; 4 or 5 stamens alternating with the petals, united at the base; a tapering ovary with 3 stigmas; erect tufted seeds, the tuft being composed of a number of hairs proceeding from the apex of the seed. The species have generally paniculated spikes of small flowers of a red colour.

T. Gallica, the Freoch Tamarisk, is a glaucous glaucous shrub, with minute acute leaves clasping the stem, with slender lateral spikes of flowers five times longer than broad. This species is a native of France, and also along the Mediterranean; it is also a native of the coasts of Cornwall, Hampshire, and Sussex, in England. Ehrenberg has described a great number of varieties of this species, one of which, the *T. G. mannifera*, known by its glaucous powdery appearance, he says, produces the manna of Mount Sinai. This is one of the species

of this genus remarkable for the large quantity of sulphate of soda which its ashes contain.

T. Indica, the Indian Tamarisk, is a glabrous greenish plant, with stiff twiggy branches; short ovate-acute leaves with white edges; elongated spikes of flowers, with bracts shorter than the flowers and longer than the pedicels, and stamens longer than the corolla. This plant is a native of the East Indies. It is subject to the attacks of a cynips, which produces galls that possess astringent properties, and, according to Dr. Royle, they are on this account used in medicine by the native doctors of India. The same property also renders them valuable in dyeing. Other Indian species of the Tamarisk produce galls, which are used for the same purposes as those of *T. Indica*.

T. Africana, the African Tamarisk, is a glabrous glaucous shrub, with lanceolate imbricated leaves; with dense, scaly, simple, sessile racemes; with ovate chaffy bracts; and a 3-valved capsule. This is a native of the sands along the shores of the Mediterranean. It is found in Mauritania, around the Bay of Naples, in Egypt, and in the Levant. It has very much the appearance of *T. Gollica*, but its flowers are larger, and the bark darker. Like *T. Gollica*, its ashes yield a large quantity of sulphate of soda.

T. orientalis, the Eastern Tamarisk, is a tree attaining a height of from 10 to 20 feet; it is glabrous all over, with minute, distant, sheathing, mucronate leaves, with slender lateral spikes of flowers, and a 4-valved capsule. This tree is a native of Arabia, Persia, and the East Indies, and is one of the largest and most elegant of the species of the Tamarisk. One of the finest specimens of this tree existing is at Babylon.

TAMATIA. [BARBETS.]

TAMIAS. [SCIRIIDE.]

TAMUS, a genus of Plants belonging to the natural order *Dioscoreaceæ*. This genus is dioecious, the stamens growing on one plant, and the pistils on another. The flowers are alike in having a perianth, which is 6-parted, the calyx and corolla being indistinguishable. In the male flowers there are 6 stamens. In the female flowers the remains are seen of 6 abortive stamens; the ovary is trilocular; the style trifid, with 3 stigmas; the fruit a berry. This genus is supposed to be the *Uva Taminia* of Pliny, hence its present name.

T. communis, the Common Black Briony, has undivided cordate-acuminate leaves, and is a very common plant in hedges and thickets throughout Europe. It is a frequent plant in England. It has a long twining stem, spreading in all directions, and reaching from branch to branch of hedges and thickets: its flowers are greenish-white; the fruit is of a red colour, and hangs in bunches from its trailing branches. The berries are unwholesome, but not poisonous.

TANACE'TUM, a genus of Plants belonging to the natural order *Compositæ* and the sub-order *Corymbifera*. The florets of the disc hemispherical, the involucre hemispherical imbricated, the receptacle naked, the fruit oblong and angular, with a large epigynous disc crowned with a slight membranous border.

T. vulgare, Taney, has pinnatifid leaves and serrated leaflets. The heads in a terminal corymb. The florets of a bright-yellow. The fruit with an entire crown. The stem is from 1½ to 3 feet high, erect, and rather angular. The root moderately creeping. Every part of the plant is hitter, and emits a strong but not unpleasant scent. It is found by roadsides in Europe and the Crimea.

TANAGER. [TANAGRINÆ.]

TANAGRINÆ, or TANAGERS, a tribe of Birds belonging to the family *Fringillidæ*. The genus *Tanagra* of Linnaeus stands, in the 12th edition of the 'Systema Naturæ,' between *Emberiza* and *Fringilla*, in the order *Passeræ*. [FRINGILLIDÆ.]

Cuvier characterises the genus as having a conical bill, triangular at its base, slightly arched at its arête, and notched towards the end: wings and flight short. He observes that they resemble our sparrows in their habits, and seek for seeds as well as berries and insects. The greater part, he remarks, force themselves upon the attention of the spectator of an ornithological collection by their vivid colours. He places the genus between the Drogons (*Edolius*, Cuv.) and the Thrushes (*Turdus*, Linn.), thus subdividing it:—

1. The Enphonous or Bullfinch Tanagers (Euphones ou Tangaras Bouvreuils).

These have a short bill, presenting, when it is seen vertically, an enlargement on each side of its base: tail short in proportion. Ex. *Tanagra violacea*, *T. Cayennensis*, &c.

2. The Grosbeak Tanagers.

Bill conic, stout, convex, as wide as it is high; the back of the upper mandible rounded. Ex. *T. magna*, *T. atra*, &c.

3. Tanagers, properly so called.

Bill conic, shorter than the head, as wide as it is high, the upper mandible arched and rather pointed. Ex. *T. Talao*, *T. tricolor*, &c.

4. Oriole Tanagers (Tangaras Loriots).

Bill conic, arched, pointed, notched at the end. Ex. *T. gularis*, *T. pileata*, &c.

5. Cardinal Tanagers.

Bill conic, a little convex, with an obtuse projecting tooth on the side. Ex. *T. cristata*, *T. brunnea*, &c.

6. Ramphocele Tanagers.

Bill conic, with the branches of the lower mandible convex, backwards. Ex. *T. Jacapa*, *T. Brasilia*, &c.

Mr. Swainson makes the *Tanagrini*, which he places between the *Coccothraustini* and the *Fringillini*, consist of the following genera and sub-genera, all of which he characterises:—

Tanagrini.—Bill equally conic; the upper mandible more or less arched, and very distinctly notched; feet formed for perching; claws broad and fully curved.

Tardivola, *Tanagra* (with the sub-genera *Pitylus*, *Tanagra*, and *Ramphopsis*). *Phanisoma* (with the sub-genera *Phanisoma*, *Tachyphonus*, and *Leucopygia*). *Nemosia*. *Aglaia* (with the sub-genera *Euphonia* and *Tanagrella*). And *Pipilo* (with the sub-genus *Arremon*). ('Classification of Birds.')

Prince Bonaparte places the *Tanagrini* between the *Fringillini* and the *Emberizini*.

Mr. G. R. Gray makes the *Tanagrini* the third sub-family of the *Fringillidæ*, arranging it between the *Coccothraustini* and *Fringillini*. The following genera are enumerated by Mr. Gray as belonging to it:—

Emberizoides, Temm.; *Pipilo*, Vieill.; *Embernagra*, Less.; *Arremon*, Vieill.; *Cissopis*, Vieill.; *Pitylus*, Cuv.; *Tanagra*, Linn.; *Saltator*, Vieill.; *Spindalis*, Jard. and Selby; *Ramphopsis*, Vieill.; *Lampprotes*, Sw.; *Pyrranga*, Vieill.; *Lanio*, Vieill.; *Tachyphonus*, Vieill.; *Nemosia*, Vieill.; *Tanagrella*, Sw.; *Euphonia*, Desm.; *Calospiza*, G. R. Gray; *Stephanophorus*, Strickl.; *Cypsnagra*, Less.

Tanagra rubra, the Scarlet Tanager, or Black-Winged Summer Red-Bird. The male is scarlet-red, with the wings and notched tail black: the base of the plumage is ash, then white. The female, young, and male in autumn, are dull-green, inclining to yellow in the latter: yellow beneath; wings and tail dusky. Length about 6½ inches; alar extent 10½ inches. It is a native of the United States of America.

"This splendid and transient resident," says Nuttall, "accompanying fine weather in all his wanderings, arrives from his winter station in tropical America from the beginning to the middle of May, and extends his migrations probably to Nova Scotia as well as Canada. With the shy, unsocial, and suspicious habits of his gaudy fraternity, he takes up his abode in the deepest recesses of the forest, where, timidly flitting from observation, he darts from tree to tree like a flashing meteor. A gaudy sylph, conscious of his brilliance, and the exposure to which it subjects him, he seems to avoid remark, and is only solicitous to be known to his humble mate, and hid from all beside. He therefore rarely approaches the habitations of men, unless perhaps the skirts of the orchard, where he sometimes however builds his nest, and takes a taste of the early and inviting though forbidden cherries.

"Among the thick foliage of the tree in which he seeks support and shelter, from the lofty branches, at times, we hear his almost monotonous 'tship-witee, tship-idee,' or 'tshukadee, tshukadee,' repeated at short intervals, and in a pensive under-tone, heightened by the solitude in which he delights to dwell. The same note is also uttered by the female when the retreat of herself and young is approached; and the male occasionally utters, in recognition to his mate, as they perambulate the branches, a low whispering 't'ait,' in a tone of caution and tenderness. But besides these calls on the female, he has also, during the period of his incubation, and for a considerable time after, a more musical strain, resembling somewhat, in the mellowness of its tones, the song of the Fiftling Baltimore. The syllables to which I have hearkened appear like 'tshooee wait wait, vehowit wait,' and 'wait, rehōwit vea wait,' with other additions of harmony, for which no words are adequate. This pleasing and highly musical meandering ditty is delivered for hours, in a contemplative mood, in the same tree with his busy consort. If surprised, they flit together, but soon return to their favourite station in the spreading boughs of the shady oak or hickory. This song has some resemblance to that of the Red-Eyed Vireo in its compass and strain, though much superior, the 'wait wait' being whistled very sweetly in several tones, and with emphasis; so that, upon the whole, our *Pyrranga* may be considered as duly entitled to various excellencies, being harmless to the farmer, brilliant in plumage, and harmonious in voice."

The same author describes the nest (which is built about the middle of May, on the horizontal branch of some shady forest tree, commonly an oak, but sometimes in an orchard tree) as but slightly put together, and usually framed of broken rigid stalks of dry weeds or slender fir-twigs, loosely interlaced together, and partly tied with narrow strips of Indian Hemp (*Apocynum*), some slender grass-leaves, and Pea-Vine runners (*Amphicarpæ*), or other frail materials; the interior being sometimes lined with the slender wiry brown stalks of the Canadian Cistus (*Helianthemum*), or with slender pine-leaves; the whole so thinly platted as to admit the light through the interstices. The three or four eggs are dull blue, spotted with two or three shades of brown or purple, most numerous towards the larger end. As soon as their single brood, which is fledged early in July, is reared, they leave for the south, generally about the middle or end of August.

"The female," he says, "shows great solicitude for the safety of her only brood; and, on an approach to the nest, appears to be in great distress and apprehension. When they are released from her more immediate protection, the male, at first cautious and distant,

now attends and feeds them with activity, being altogether indifferent to that concealment which his gaudy dress seems to require from his natural enemies. So attached to his now interesting brood is the Scarlet Tanager, that he has been known, at all hazards, to follow for half a mile one of his young, submitting to feed it attentively through the bars of a cage, and, with a devotion which despair could not damp, roost by it in the branches of the same tree with its prison."

The food of this species consists mostly of winged insects, such as wasps, hornets, and wild bees, the smaller kind of beetles, and other *Colcoptera*. Seeds are supposed to be sometimes resorted to, and they are very fond of whortle and other berries.

It is in August that the moult of the male "when he exchanges his nuptial scarlet for the greenish-yellow livery of the female," commences. ('Manual of the Ornithology of the United States and of Canada.')

TANGHIN POISON. [CERBERA.]

TANGHINIA, a genus of Plants belonging to the natural order *Apocynaceæ*. It has an infundibuliform corolla, with a clavate tube, and 5-toothed throat; the anthers are subsessile. The fruit is a drupe, with a fibrous ligneous putamen or stone, which contains one or two seeds. The specific name, *T. venenifera*, was given to the plant which yields the poison. It has dense leaves, with erect branches, and paniculated terminal flowers. In its native island this plant attains the size of a tree, and has a hard wood, which may be used for many kinds of carpentry; but the part which yields the poison is the kernel of the fruit. Although this kernel is small, not much larger than an almond, Mr. Telfair says that it contains enough poison to kill twenty persons. Its great use in Madagascar was as a means of trial, the innocent being supposed able to resist its action, whilst the guilty suffered under its influence.

TANGLES. [ALGÆ.]

TANSY. [TANACETUM.]

TANTALIDÆ. [SCOLOPACIDÆ.]

TANTALITE. [COLUMBITE.]

TANTALUS. [ABOU-HANNES; SCOLOPACIDÆ.]

TANYSIPTERA. [HALCYONIDÆ.]

TAP-ROOT. [ROOT.]

TAPE-WORM. [ENTOZOA.]

TAPHOZO'US. [CHEIROPTERA.]

TAPIO'CA. [FOOD; JANIPHA.]

TAPIRUS, *Tapir*, the name of a genus of Animals belonging to the family *Pachydermata*.

Linæus does not notice the Tapir in the 12th (his last) edition of the 'Systema Naturæ:' but Gmelin quotes it as the '*Hippopotamus* (terrestris) pedibus posticis trisulcatis.' ('Syst. Nat.')

Gmelin introduces it under the title *Tapir*, between *Hippopotamus* and *Sus*.

Cuvier arranges the genus as the last of his *Pachydermes Ordinaires*, making it immediately succeed the extinct *Palæotheria* and *Lophiodons*. The genus was well known to the older zoologists who wrote on the natural products of America.

frontal bones: these are early united and directed a little backwards. At the middle of the base of this triangle, to which the bones of the nose are articulated, is a point which penetrates between them; and from the two sides above the orbits descends a deep furrow produced by the structure of the upper border of the orbit, and which approaches towards the suborbital hole: it serves for the insertion of the muscles of the proboscis. The orbit descends lower than the mid-height of the head, is very wide, and has the postorbital apophyses but little marked.

The lower jaw exhibits a striking width at its ascending ramus, and presents a rounded contour backwards at its posterior angle. Its coronoid apophysis elevates itself in the form of a pointed falx above the condyle, which is transverse and large. The two jaws are a little concave laterally at the vacant interval of the teeth, and are very much narrowed there; their edge is treacherant.

Skull of American Tapir.

The lateral apophyses of the atlas are wide, but little extended outwards; the spinous process of the axis is an elevated crest; the transverse processes are small and irregular; the odontoid is large and obtuse; the transverse processes of the three succeeding vertebrae descend obliquely, are a little widened at the end, and cut nearly square; their spinous processes are very small. The fifth cervical vertebra has a small apophysis on its transverse process, which, for the rest, resembles that of the preceding vertebra, but is rather longer; its spinous process is also rather longer; still more is that of the seventh vertebra, the transverse process of which is very small—in short, a simple tubercle. The articular facets of the cervical vertebrae rise obliquely from within outwards, so that the articular facet of one vertebra is below that which responds to the preceding vertebra. The bodies of the vertebrae are convex forward and concave behind, an organisation which is more or less repeated in the rest of the spine. The number of dorsal vertebrae amounts to twenty; the spinous apophysis of the second is the longest. They decrease and incline backwards to the eleventh, from which they become

Skeleton of American Tapir.

When viewed in profile, the pyramidal elevation of the skull of the Tapir, calling to mind what is to be seen in the hog, strikes the observer forcibly. But the pyramid of the Tapir differs from that of the hog in having only three faces; and also in this, that its anterior line is formed by the meeting of the lateral faces, and it is only towards the front that it is dilated into a triangle, which is due to the

straight, square, and nearly equal. Their articular apophyses are so fitted that those of one vertebra are in advance and above those which correspond with it in the vertebra below. Cuvier found twenty pairs of ribs in one individual, nineteen in another, eight of which are true, all slender and rounded for the greatest part of their length. The breast-bone is composed of five bones; its anterior portion is com-

pressed, and projects in the form of a plough-share. There are four lumbar vertebrae, the transverse apophyses of which are rather large. Those of the last, which are rather shorter and oblique, are articulated with the first sacral vertebra. These transverse apophyses have on their base the same elevated crests as the dorsals have for articulation with the ribs. The os sacrum of the adult consists of seven vertebrae, the spinous apophyses of which are distinct and inclined backwards; the last five of these apophyses are short and terminate by a widened disc. The tail has seven vertebrae.

The bones of the extremities are remarkably strong, and in many points resemble those of the Rhinoceros, especially the bone of the carpus.

Cuvier, in his osteological comparison of the Indian Tapir with the American form, observes that a glance at the profile of their respective crania is sufficient to impress upon the observer their specific differences. The forehead of the Indian Tapir is, he observes, so convex, that it rises higher than the occiput: it elevates in its rise the nasal bones, which much prolongs the ascending part of the jaws and the descending portion of the frontal bones along the external aperture of the bony nostrils, thus giving much wider room for the comparatively large proboscis, and adding length to the furrows where the muscles are inserted. This organisation, he observes, explains why the Indian Tapir has a more powerful and extensible trunk than that of the American Tapir. There is even, he adds, in the Indian species, on the base of the nasal bones at their junction with the frontal bones, and on each side, a deep fossa which does not exist in the other species. This elevation of the forehead is accompanied by a depression of the occipital crest, which, far from forming a pyramid, as in the American species, rather descends backwards. The aperture of the bony nostrils, so enlarged by the prolongation of the maxillary bones, terminates below and forwards by more elevated intermaxillaries, which are for the rest anchylosed together in early youth as in the American Tapir.

The interval between the canine and the first molar is less in proportion in the Indian Tapir, whose dentition is otherwise the same with that of the American species.

The zygomatic apophysis of the Indian species is a little higher backward and less forward: its mastoid apophysis is more transversely turned.

Cuvier remarks that the rest of the skeleton of the two species does not offer such appreciable differences.

Mr. Yarrell, in the fourth volume of the 'Zoological Journal,' gives an account of the post-mortem appearances in an American Tapir brought to this country by Lieutenant Maw, R.N., which survived its arrival in the gardens of the Zoological Society in the Regent's Park only a few hours.

When dead, the animal, which was said to be about 12 months old, measured from the nose to the root of the tail 48 inches, and its girth was 35 inches.

Dental Formula:—Incisors, $\frac{6}{6}$; Canines, $\frac{1-1}{1-1}$; Molars, $\frac{4-4}{3-3} = 30$.

The incisor teeth were very much used, the edges coming into close contact when the molars are in action. The canines were small in the upper jaw, and removed a short distance from the lateral incisor, for the admission of the larger canines of the lower jaw.

Mr. Yarrell refers to Sir Everard Home's paper in the 'Philosophical Transactions' (1821), in which Sir Everard points out the differences existing in the skulls of the Sumatran and American Tapirs, and has described a part of the viscera of the former. In the Sumatran Tapir the stomach is large, the intestinal canal very long, and the caecum small; in the American Tapir the stomach is small, the intestines of moderate length, and the caecum large.

Mr. Yarrell adds that, of the species described, the length of the Sumatran Tapir is 8 feet; and the whole length of its intestinal canal is 89 feet 6 inches. Proportion as 11 to 1.

The length of the American Tapir is 4 feet; and the whole length of its intestinal canal 28 feet. Proportion as 7 to 1.

Tapirus has the following generic characters:—Molars presenting on their crown before they are worn two transverse and rectilinear tubercles (collines); nose terminated in a small moveable proboscis, but not terminated with an organ of touch like that of the Elephant; neck rather long; skin rather thick, and covered with hair, looking as if it had been close shorn; two inguinal mammae. Anterior feet with four toes; posterior feet with three toes.

The species are found in Asia and America. The dental formula of the Asiatic species is as follows:—

Incisors, $\frac{6}{6}$; Canines, $\frac{1-1}{1-1}$; Molars, $\frac{7-7}{6-6} = 42$.

T. Malayanus (*T. Indicus* of the French zoologists; Le Malba, F. Cuv., 'Mamm.'), the Asiatic Tapir. "The Malay Tapir resembles in form the American, and has a similar flexible proboscis, which is six or eight inches in length. Its general appearance is heavy and massive, somewhat resembling the Hog. The eyes are small; the ears roundish, and bordered with white. The skin is thick and firm, thinly covered with short hair. There is no mane on the neck, as in the American species. The tail is very short, and almost destitute of hair. The legs are short and stout; the fore feet furnished with four toes, the hind feet with three. In the upper jaw there are seven

molars on each side, one small canine inserted exactly on the suture of the incisor bone, and in front six incisors, the two outer of which are elongated into tusks. In the under jaw there are but six molars; the canines are large; and the number of the incisors, the outer of

Teeth of Sumatran Tapir.

which are the smallest, is the same as in the upper jaw. The general colour is glossy black, with the exception of the back, rump, and sides of the belly, which are white, and separated by a defined line from the parts that are black." (Raffles.)

The habits of this species in a state of nature are probably similar to those of the American Tapirs. In captivity, Major Farquhar describes it as of a mild and gentle disposition. "It became as tame and familiar as a dog; fed indiscriminately on all kinds of vegetables, and was very fond of attending at table to receive bread, cakes, or the like." Sir Stamford Raffles adds, that the living specimen sent from Bencoolen to Bengal was young, and became very tractable. It was allowed to roam occasionally in the park at Barrackpore, and the man who had charge of it informed Sir Stamford that it frequently entered the ponds, and appeared to walk along the bottom under water, and not to make any attempt to swim. Sir Stamford also states that the flesh is eaten by the natives of Sumatra.

The individuals which have been exhibited in the Regent's Park Gardens have been very mild and gentle.

T. Americanus (Gmel.), the American Tapir. General colour throughout deep brown approaching to black. Sides of the lower lip, hand on the under and middle part of the chin, upper edges of the ears, and naked line at the bottom of the hoofs, pure white. Scanty hair of the body very short, closely adpressed to the surface, hardly distinguishable at a short distance. The skin beneath it is of great density, being, according to M. Roulin, not less than seven lines thick on the back, and eight or nine lines on the cheek, and so tough that Sonnini frequently shot at a female which was crossing the river with her young without disturbing her or making her turn out of her course, though he saw the impression of a ball which he had fired on the animal's cheek. There is a thick rounded crest on the back of the neck, extending from the forehead as low as the level of the eyes to the shoulders, and bristled with a not thick mass of stiff blackish hairs. Mr. Bennett remarks that it is peculiar to the present species, but is not found, according to M. Roulin, in the female of Guyana; although D'Azara states that the female is equally furnished with it in Paraguay. In the female brought by Lieut. Maw from Para, and formerly in the menagerie of the Zoological Society of London, it was very conspicuous. Head very long; muzzle prolonged and covered above with hair of the same colour as that of the body, but naked and flesh-coloured at its extremity (which is flattened) and underneath; eyes very small, of a dull lead-colour.

Malay Tapir (*Tapir Malayanus*).

The colour of the individual dissected by Mr. Yarrell was rusty reddish-brown, with indications of lighter spots and horizontal lines on the ribs, flanks, and thighs. "These fawn-coloured spots and stripes," says Mr. Yarrell, "are common to both species of Tapir [the Sumatran and the American species then known as meant] while young; that of Sumatra not exhibiting till it is six months old any appearance of the well-defined black and white colour which afterwards distinguishes the adult animal." ('Zool. Journ.,' vol iv.)

This species is a native of South America. "Few animals of equal size," says Mr. Bennett, "have so extensive a range as the American Tapir. It is found in every part of South America to the east of the Andes, from the Straits of Magellan to the Isthmus of Darien; but appears to be most common within the tropics. M. Roulin dwells upon it as a singular fact that although it occurs as far as 40° south of the equator, it ceases suddenly at about 8° north, in a situation where it is extremely abundant, and where no adequate cause has yet been assigned to bar its further progress, no large rivers nor lofty mountains intervening, nor any change in the character of the vegetation of the country being manifest. The left bank of the Atrato near its mouth, and the part of Darien inhabited by the independent Indians, may be considered as its northern limit. Its highest range, in the province of Maraquita at least, appears to be from 3000 to 3600 feet above the level of the sea, while the new species discovered by M. Roulin is only met with at a much greater elevation."

The inmost recesses of deep forests are the chosen haunts of this species, which is not gregarious, and flies from the proximity of man. It is for the most part nocturnal in its habits, sleeping or remaining quiet during the day, and at night seeking its food, which, in its natural state, consists of shoots of trees, buds, wild fruits, &c. If we are to believe D'Azara, and he was an accurate observer, it is very fond of the barréro, or nitrous earth of Paraguay. It is however a most indiscriminate swallower of everything filthy or clean, nutritious or otherwise, as the farrago found in the stomach of the individual dissected by Mr. Yarrell showed. Pieces of wood, clay, pebbles, and bones are not unfrequently taken out of the stomachs or those which are killed in the woods; and one kept by D'Azara gnawed a silver snuff-box to pieces and swallowed the contents.

It is a powerful animal, and everything in the underwood of the forest gives way to its rush. It is in the habit of making runs or roads through the brushwood, and these beaten tracks are usually selected by travellers in passing through the forests.

Quiet and peaceable in its demeanour, it is hunted for the sake of its tough hide and its flesh, which, though not liked by the European (for it is coarse and dry), is relished by the unsophisticated palate of the Indian.

The lasso is not often employed in its capture, not only from its haunts being generally unfavourable to that mode of hunting, but because its determined rush and strength will at a single effort snap the line which is strong enough to arrest the career of a bull. The hunters will sometimes lie in wait with their dogs near a Tapir's road

as evening approaches, and so get between him and the water to which he usually directs his course for the purpose of bathing and wallowing at the commencement of his nocturnal career. He makes a good fight, and inflicts severe wounds upon the dogs with his teeth, especially if he can reach the water, where he stands at bay, breast deep, and defies the fiercest of them; for as they are compelled to swim to the attack, the Tapir bides his time, and seizing them by the backs of their necks as they successively come within his reach, shakes them off, not without biting a piece out.

But it would seem that the most common method of catching them is by imitating their sharp but not very shrill whistle, and thus bringing them within shot of the Indian's poisoned arrow.

Lieut. Maw, who brought a young animal of this species to England, speaks of it as feeding upon herbs and the branches of trees, and going much into the water, walking along or rather perhaps across the bottoms of rivers.

This species is mild in captivity, and easily domesticated. Sonnini states that tame Tapirs are permitted to go at liberty through the streets of the towns of Guyana, and to wander into the woods, whence they return in the evening to the house where they are kept and fed. He adds that they are capable of attachment to their owner, and expresses his opinion that care and attention might convert its qualities of strength, docility, and patience, to account as a beast of burden.

American Tapir (*Tapirus Americanus*).

But this is not the only American Tapir; for M. Roulin laid before the French Academy a description and figures of a new species inhabiting the mountainous parts of the same districts, the plains of which are frequented by the other; and his account is given in the 'Annales des Sciences Naturelles': from this it would appear that the American Tapir of the mountains is more nearly allied to the Asiatic species than the American Tapir of the plains.

The Tapirs are closely allied in structure to the fossil genus *Palæo-*

therium. Three species, *T. Mastodontoides*, *T. priscus*, and *T. Avernensis* have been described as fossil, occurring in the tertiaries of France and Germany. The fossil genera, *Coryphodon* and *Lophiodon*, are referred by Professor Owen to the *Tapiroidea*. [CORYPHODON; LOPHIODON; PALEOTHERIUM.]

TAR, a resinous product obtained from the burning of the wood of *Conifera*. [TAR, in ARTS and SC. DIV.]

TARAGUIRA. [IGUANIDÆ.]

TARANDUS. [CERVIDÆ.]

TARANTULA, the *Aranea Tarantula* of Linnæus, a species of spider of the genus *Lycosa* of Latreille. It is one of the largest of European spiders, and is found in the countries bordering the Mediterranean, where its bite is dreaded, and believed to be curable only through the effects of music. In reality however its venomous powers have been greatly exaggerated. According to Walcknaer several distinct species have been confounded under the name of *Tarantula*.

TARDIGRADA, Cuvier's name for the first family of the *Edentata*, comprising, of living genera, the Sloths only. [AI; UNAU.] The *Tradigrada* form the eighth order in Illiger's method, and comprise the Sloths and *Prochilus*; but the latter cannot be said to have any claim to such a collocation. [BRADYPUS; BEAR.]

TARDIVOLA (Swainson), a genus of Birds belonging to the sub-family *Tanagrina*.

TARRAGON. [ARTEMISIA.]

TARSIUS (Storr), a genus of Animals belonging to the family *Quadrupana*. It has the following characters:—Head rounded; muzzle short; eyes very large; posterior limbs very much elongated, with the tarsus thrice as long as the metatarsus. Tail long.

Dental Formula:—Incisors, $\frac{4}{2}$; Canines, $\frac{1-1}{1-1}$; Molars, $\frac{6-6}{6-6}=34$.

T. Bancanus. Dr. Horsfield remarks, that although the *Tarsius* from Banca agrees in the essential points with the other species of this singular genus which have hitherto been discovered, it has no intermediate front teeth, and the exterior tooth on each side is, compared with the other species, very minute. Counting (with Desmarest) one canine tooth on each side, above and beneath, it has, says Dr. Horsfield, only five grinders in each jaw.

Teeth of *Tarsius*, much larger than the natural size. (P. Cuvier.)

Front view of the Teeth of *Tarsius Bancanus*. (Horsfield.)

The hands of this creature are small and delicate, and externally covered with a very soft down. Internally they are naked. The nails

of all the fingers of the hand, as well as of the thumb and the third and fourth finger of the feet, are triangular, and represent a delicate compressed scale: on the index and middle finger of the feet they are erect, sharp, compressed, slightly curved, and not inaptly compared by Mr. Fischer to the thorns of a rose-bush, constituting one of the essential characters of this genus. The body is handsomely formed, and, as in the other species, somewhat contracted towards the pelvis; the lower extremities also have in general a similar character, but the tarsus has less of the extravagant length which is common to the other *Tarsii*. The fur is remarkably soft to the touch; it is composed of a thick and very delicate wool, which envelops the body, head, and extremities, forming a coat of an unequal surface, from which irregular straggling hairs project; at the root of the tail, and at the hauds of both extremities, it terminates abruptly in the form of a ring. The general colour is brown, inclining to gray; on the breast, abdomen, and interior of the extremities it is gray, inclining to whitish; a rufous tint is sparingly dispersed over the upper parts, which shows itself most on the head and extremities; the naked parts of the tail near the root are considerably darker than the extremity. ('Zoological Researches in Java.')

Dr. Horsfield obtained this animal in Banca, near Jeboos, one of the mining districts, where, he says, it inhabits the extensive forests in the vicinity.

Tarsius Bancanus. (Horsfield.)

TARSUS. [SKELETON.]

TARTAR. [POTASSIUM.]

TATOUAY. [ARMADILLO.]

TAUTOLITE, a Mineral which occurs crystallized. Primary form a right rhombic prism. Fracture conchoidal, uneven. Hardness 6.5 to 7. Very brittle. Colour velvet-black. Streak gray. Lustre vitreous. Opaque. Specific gravity 3.865. Before the blow-pipe, on charcoal, melts into a blackish scoria, which is attracted by the magnet: with borax it forms a clear green glass.

It is probably a silicate of protoxide of iron, and silicate of magnesia. It is found in the volcanic rocks of the Lake of Laach, near Bonn, on the Rhine.

TAXACEÆ, *Taxads*, a natural order of Plants belonging to the class *Gymnosperma*. This order possesses the following essential characters:—The flowers are monœcious or diœcious, and are naked, or solitary surrounded by imbricated bracts, or in spikes surrounded by bracts. The male flowers have no calyx, and several stamens, mostly united at the base, with the anthers either combined or distinct. The female flowers are solitary and naked; the ovules are naked, with the foramen at the apex. The seeds are hard, and are sometimes surrounded by a succulent, coloured, cup-shaped pericarp; they possess fleshy albumen, and a straight dicotyledonous embryo. The plants of this order are trees or shrubs, having a woody tissue marked with circular discs, with evergreen and mostly narrow rigid entire and veinless leaves.

This order is very characteristic of the class to which it belongs, in the absence of any regularly formed ovary, and the consequent exposed or naked state of the ovule and seeds. In this respect it

offers a lower state of organisation than the *Conifera*, or Pine Tribe, the ovules of which have a kind of protection in the hardened scale-like bracts which constitute the cones of that order. The foliage also of *Taxaceæ* differs from *Conifera* in their possessing a greater tendency to expand and form veins within their tissue. In the few species of *Taxaceæ* that possess veins, they are not straight and parallel, as in *Endogens*, but are forked and of a uniform thickness, similar to those possessed by the higher forms of *Cryptogamia*, as the Ferns.

This order consists of plants that are but thinly distributed on the surface of the earth. They are mostly natives of temperate parts of Europe, Asia, Africa, and America. The order yields trees which are valued for their timber, and, like *Conifera*, possess resinous properties. The branches of the *Dacrydium taxifolium* are used in New Zealand for making spruce-beer. [TAXUS; SALISBURIA.]

TAXICORNES, the second family of the Heteromorous *Coleoptera*, in Latreille's arrangement of Insects. They have no corneous tooth on the inner side of the maxillæ; they are all winged insects, with nearly square bodies, and a thorax which conceals or receives the head; they have short antennæ, and legs adapted for walking only. They live in *Fungi*, beneath the bark of trees, or on the ground under stones. This family is divided into two tribes, of which the genera *Diaperus* and *Cossypus* are respectively the types.

TAXITES, a genus of Fossil Plants from Stonesfield.

TAXO'CRINUS. [ECHINODERMATA.]

TAXO'DIUM (from 'taxus'), the name of a genus of Plants belonging to the natural order *Conifera*. The plants of this genus are monœcious. The male flowers are arranged in catkins of a roundish form, disposed in racemose panicles; the pollen of each flower is contained in five cases, which are attached to the scale at its inner face. The female flowers are also arranged in small round catkins, two or three of which are attached near to the base of the spike of the catkins of male flowers. The ovules are two in each receptacle. The fruit is a globose strobule, with peltate-angled scales; the seeds are angled with very thick integuments; the embryo with from 5 to 9 cotyledons. The leaves are linear, disposed in two ranks, and are deciduous. This genus has been distinguished from *Cupressus*, principally on account of the arrangement of its male catkins in racemose panicles, the small number of flowers in the female catkins, and the numbers of cotyledons possessed by the embryo.

T. distichum, Deciduous Cypress. This tree was introduced into Europe from North America as early as 1640. It is characterised by two-rowed, flat, deciduous leaves; leafless and paniced male flowers, and somewhat globose strobili. It is an elegant tree, and attains a height of 120 feet in its native soil. The first plant that is mentioned as existing in this country was grown in South Lambeth, and was raised from seeds brought from Virginia. Since then it has been introduced in various parts of Great Britain, and many fine specimens are now to be found. In its native districts in North America it is exceedingly abundant, and in many parts, as in Louisiana, it entirely occupies thousands of acres of the low grounds, which are thence called *Cyprières*, or *Cypress Swamps*. It is found in Delaware, on the banks of the Indian River, in 38° 50' N. lat., which is its northern boundary, and proceeding southward it is abundant in the swamps of Virginia, the Carolinas, Georgia, and Florida.

In America, where the tree grows, its wood is used for all the purposes to which timber is applied. A number of varieties have been named. The most common is the *T. d. patens*, which has horizontal branches. Another, with pendulous branches, is known as *T. d. pendulum*; a third, with pendulous first year's shoots, as *T. d. nutans*. Other species of the genus have been described, but are not yet used or cultivated.

(London, *Arb. et Frut. Brit.*, vol. iv.)

TAXUS ('taxus', Latin), the name of a genus of Plants, the type of the natural order *Taracææ*. This genus is monœcious; the perianth of the barren flowers is single at the base; the stamens are numerous, with peltate anthers 6-8-celled, the opening beneath. The fertile flowers have a single urceolate scaly perianth; no style; and a fleshy drupaceous fruit, perforated at the extremity. The species of this genus are evergreen trees, with numerous mostly linear entire leaves. They are natives of Europe and North America.

T. baccata, Common Yew, has its leaves 2-ranked, crowded, linear, flat, with the flowers axillary, sessile; the receptacle of the barren flowers globular. The common yew is well known. It is indigenous to most parts of Europe, and is found in every part of Britain and Ireland. It is seldom seen growing in company with its own species, but alone, or with other species of plants.

The yew is a low tree, the trunk rising 3 or 4 feet from the ground, and then sending out numerous spreading branches, forming a head of dense foliage, which, when full grown, may be sometimes 30 or 40 feet high. It is of slow growth, attaining under favourable circumstances a height of 6 or 8 feet in ten years, and 15 feet in twenty years. The tallest yew in England is in the churchyard at Harlington, near Hounslow, and is 58 feet high. A tree continues growing for about 100 years; it mostly ceases to grow at that age, but will live for many centuries. The yew-trees at present existing at Fountains Abbey in Yorkshire are supposed to have attained their full growth when the abbey was erected in 1132.

NAT. HIST. DIV. VOL. IV.

The remarkable characters and properties of the Yew have drawn towards it at all times much attention. Dioscorides, Pliny, and Theophrastus, mention its poisonous properties. Cæsar ('Bell. Gall.' vi. 31) relates that Cativolcus, king of the Eburones, committed suicide by swallowing the juice of the Yew. Plutarch says that its fruit is poisonous, and that its shade is fatal to all who sleep under it. This is also stated by Pliny; but there must have been some mistake on some of these points, as it is now well known that the fruit of the Yew may be eaten with impunity, and that its shade is not more deadly than that of other trees.

The Yew appears to have been employed from the earliest times in the manufacture of bows, and was used for this purpose by the nations of antiquity. The bows used by the English previous to the introduction of gunpowder were made of Yew, and there are many allusions amongst English poets to this use of its wood.

There are several remarkable specimens of old Yews existing in this country. Those at Fountains Abbey are said to have sheltered the monks whilst that magnificent pile was erecting. The Tytherley, Fortingal, Arlington, and Loch-Lomond Yews are remarkable for their size and age. Many of them, if we estimate their age in the mode proposed by De Candolle, must exceed considerably a thousand years.

TEA. [THEA.]

TEA, PARAGUAY, or MATE', is the produce of a plant belonging to the family *Aquifoliaceæ*. It was formerly supposed to be the produce of the *Ilex vomitoria*, which is found in North America, in the Carolinas, and Florida; but, from specimens sent from Brazil to Mr. Lambert, it appears to be a distinct species, which he has named *Ilex Paraguayanensis*. It is a shrub attaining the size of the orange-tree; it is quite smooth, with bluntish wedge-shaped remotely serrated leaves, with umbelliferous flowers seated in the axils of the leaves. It is the *Ilex Maté* of Saint Hilaire, and grows wild in Paraguay and Brazil, and is called by the Spaniards *Yerva Maté*. The leaves of this shrub are in great repute amongst the inhabitants of South America, and are used in infusion in a similar manner to the Tea of China. Upwards of 5,000,000 lbs. of the leaves of this tree are annually collected in Paraguay, and are sent to Chili and the viceroyalty of Buenos Ayres. It is not cultivated, and merchants carry various articles of use into the interior, which they give the natives for their labour in collecting the leaves of the plant. After the branches are cut away, the ground is heated by means of a fire, and the branches being laid upon the heated ground, are dried, and afterwards they are beaten and pressed into hags, in which state it comes into the market. There are three kinds known in the market: the *Caa-Cuys*, which is the bud of the leaf; the *Caa-Mini*, the leaf torn from its midrib and veins without roasting; and the *Caa-Guazu*, or *Yerva de Palos* of the Spaniards, the whole leaf with the petioles and small branches roasted. The first does not steep well, and is seldom seen. The plant when used is steeped in boiling water, to which a little sugar and sometimes lemon-juice is added. It is drunk out of a vessel called *maté*, which has a spout perforated with holes for the purpose of preventing the powdered herb from passing out with the fluid. The Creoles are passionately fond of this infusion, and never partake of a meal without it. The properties of this plant are sedative and stimulant.

Another species of *Ilex*, the *I. Gonghona*, found in Brazil, is applicable to the same purposes as the last; and although inferior in quality, was used extensively as a substitute for the true Paraguay Tea, when the export of the latter from Paraguay was forbidden by the Dictator Francia.

The *I. vomitoria* produces the Cassena of Florida and the Carolinas, which is used for the purpose of correcting the flavour of water.

TEAK. [TECTONA.]

TEAL, the common name of a Natatorial Bird belonging to the family *Anatina*. [DUCKS.] This bird is the *Querquedula crecca*, Steph.; the *Anas crecca*, Linn. It is one of the smallest of the *Anatidæ*, and most beautiful of ducks. It is the Sarcelle, Petite Sarcelle, Cercelle, Cercerelle, Alehrande, Garsote, and Halebran, of the French; *Cercedula*, *Cercevol*, *Scavolo*, *Sartella*, *Anitrella*, and *Anitra d'Inverno*, of the Italians; *Spiegel-Entlein* and *Kriekente* of the Germans; *Winter Taling* of the Netherlands; *Arta* and *Kræcka* of the Swedes; *Kestelort-And* of the Norwegians; *Krik-And* of the Danes; *Cor Hwyad* and *Brach Hwyad* of the Welsh.

This species is one of the most delicate of the ducks. Willughby remarks that, for the taste of its flesh and the wholesome nourishment it affords the body, it "doth deservedly challenge the first place amongst those of its kind."

In the 'Portraits d'Oyseaux' (1557), the following quatrains celebrate its excellence, and alludes to its habits:—

"Bien peu souvent se plonge la sarcelle
Entre deux eaux, de laquelle la chair
Est delicate: aussi couste elle cher
Autant qu'oiseau qui soit petit comme elle."

Accordingly we see it holding a high place in ancient feasts. We find it among the 'goodly provision' at the banquet given at the enthroning of George Nevell, archbishop of York, in the reign of Edward IV.: 'Mallardes and Teales, 4000.' The price in the Northumberland Household Book is—'Teyles, 1d., mallardes being 2d.

Common Teal (*Querquedula crecca*):

TEAZLE. [DIPTACUS.]

TECO'MA (from Tecomaxochitl), a genus of Plants belonging to the natural order *Bignoniaceae*. It has a campanulate 5-toothed calyx, a short-tubed corolla with a campanulate throat, and a 5-lobed bilabiate limb; 4 didynamous stamens with a sterile filament of a fifth; a bilamellate stigma; a silique-formed 2-celled capsule, having the dissepi-ments contrary to the valves; the seeds winged, disposed in 2 rows. The species are erect trees or shrubs or scandent plants, with unequally pinnate or digitate simple leaves with terminal panicles, and yellow or flesh-coloured flowers. They are natives of the Old and New World in tropical and sub-tropical climates. They are all elegant plants, and well worthy of cultivation.

T. radicans is a climbing glabrous plant with rough rooting branches. It grows against a wall by throwing out roots from its branches in the same manner as ivy. It has large flowers, which are called Trumpet-Flowers.

T. sians is a small tree. Its roots are reputed diuretic.

Several other species of *Tecoma* have reputed medicinal virtues. *T. speciosa* is said to be a useful diuretic, also a cathartic. *T. impetiginosa* and *T. Ipe* contain large quantities of tannin.

TECTIBRANCHIATA, Cuvier's name for the fourth order of Gasteropodous *Mollusca*, and described by him as having the branchiæ attached along the right side, or on the back, in form of leaves (feuillets) more or less divided, but non-symmetrical. The mantle covers them more or less, and contains nearly always in its thickness a small shell. The *Tectibranchiata* approach the *Pectinibranchiata* in the form of the organs of respiration, and live, like them, in the waters of the sea; but they are all hermaphrodites, like the *Nudi-branchiata* and the Pulmouiferous *Mollusca*. [PECTINIBRANCHIATA; NUDI-BRANCHIATA.]

The following genera are comprehended by Cuvier under this order:—*Pleurobranchus*, Cuv.; *Pleurobranchæa*, Meckel (*Pleurobranchidium*, Blainv.); *Aplysia*, Linn.; *Dolabella*, Lam.; *Notarchus*, Cuv.; *Bursatella*, Blainv.; *Akera*, Müll.; *Gastropteron*, Meckel; and *Umbrella*, Lam.

Of these, *Pleurobranchus*, *Pleurobranchæa*, and *Umbrella* are treated of in the article SEMIPHYLLIDIANS; and *Akera*, or *Acera*, and *Gastropteron*, or *Gastroptera*, under the article BULLIDÆ. *Aplysia*, or *Laplysia* (for Linneus writes it both ways), *Dolabella*, and *Notarchus* therefore remain to be noticed here.

Aplysia.—Edges of the foot raised into flexible crests and surrounding the back on all sides, being capable even of being reflected upon it; head carried on a neck more or less long; two upper tentacles hollowed like the ears of a quadruped; two others flattened at the edge of the lower lip; eyes below the first. On the back are the branchiæ, in form of very complicated leaves (feuillets), attached to a large membranous pedicle, and covered by a small pedicle equally membranous, which contains in its thickness a horny and flat shell. The anus is pierced behind the branchiæ, and is often hidden under the lateral crests. The vulva is in front on the right, and the penis comes out under the right tentacle. A furrow, which extends from the vulva to the extremity of the penis, conducts the semen at the time of coition. An enormous membranous crop leads to a muscular gizzard, armed within with cartilaginous and pyramidal corpuscles, which accompany a third stomach beset with pointed hooks, and a fourth in form of a cæcum. The intestine is voluminous. These animals feed on sea-weed (*Fucus*). A particular gland pours out by an orifice situated near to the vulva a limpid humour, which is said to be very acrid in certain species; and from the border of the mantle there oozes abundantly a deep purple liquor, with which the animal colours the sea for a considerable distance around when it perceives any danger. The eggs are deposited in long interlaced glairy filaments, ciliate as packthread.

Cuvier instances as examples from the European seas, *A. fasciata*, *A. punctata*, and *A. depilans*.

A. depilans. Blackish, with large cloudy grayish spots or blotches, or of different shades of brown tinged with blue or purple. It is found in European seas, where it adheres to rocks.

*Aplysia depilans*.

Dolabella.—Cuvier observes that this form only differs from the *Aplysia* in having the branchiæ and that which surrounds them at the posterior extremity of the body, which resembles a truncated cone. Their lateral crest, he adds, does not close on the branchial apparatus, leaving a narrow furrow, and their shell is calcareous.

The species are found in the East Indian seas and Mediterranean, where it has been found at a depth of six fathoms on sands.

D. Rumphii may be given as an example.

Shell of *Dolabella Rumphii*. a, inside; b, outside.

Notarchus.—Animal furnished with a very small dorsal slit, which is sometimes oblique; foot elongated, and rather narrow; branchiæ often very long, and capable of being protruded out of the cavity; operculum rudimentary or null; shell absent.

N. Cuvieri is an example.

*Notarchus Cuvieri*.

TECTONA, a genus of Plants belonging to the natural order *Verbenaceæ*. It is characterised by having a 5-6-toothed calyx, which becomes inflated over the growing pericarp; corolla 1-petalled, 5-6-cleft; stamens 5, but often 6; germ superior, 4-celled; axis 1-seeded, attachment central; drupe obtusely 4-sided, woolly, spongy, dry, hid in the calyx. Nut hard, 4-celled. Seed solitary; embryo erect without perisperm.

The only species is the Teak-Tree, which grows to an immense size, and is remarkable for its very long leaves, which are from 12 to 24 inches long and from 8 to 16 inches broad, and are compared by oriental writers to the ears of the elephant. The best teak-timber for ship-building was supplied to Bombay from the mountains of the Malabar Ghauts, where the tree is found rather in detached clumps, of some extent however, than in extended forests. It is also found on the mountainous parts of the Coromandel coast, along the banks of the Godavery up to Poloonsha. It proceeds far into the interior of India, and may be seen in the mountains of Bundelcund, in the form however of only a moderate-sized shrub. Dr. Roxburgh introduced the Teak into the low grounds of the Circars as early as 1790, and

Lord Cornwallis and Colonel Kyd planted it in Bengal about the same time. The Calcutta Botanic Garden contains a number of these trees. From the Saharunpore Botanic Garden, in $30^{\circ} 9' N.$ lat. (where, its buds being covered with scales, it is enabled to resist cold, besides its leaves falling and giving it a season of rest), the tree has been spread along the Doah Canal; the whole of the intermediate country is suited to its cultivation, and the East India Company have ordered the Malabar forests to be preserved. The most extensive forests are however those extending along the banks of the Irrawady, especially in Pegu. [TEAK, in ARTS AND SC. DIV.]

TECTUS. [TROCHIDÆ.]

TEESDA'LIA (named after Robert Teesdale), a genus of Plants belonging to the natural order *Cruciferae*. It has a roundish notched pouch, boat-shaped valves, their backs keeled below, narrowly winged above; the seeds two in each cell; the petals either equal or the two outer ones larger. The species are small annual herbs. The flowers usually small and white.

T. nudicaulis is the *T. Iberis* of De Candolle. It has unequal petals and numerous leaves spreading on the ground; the stamens with remarkable scales within, the pouch emarginate. It is found in sandy and gravelly places in England, France, Germany, Denmark, and Sweden. It is the only British species. *T. lepidium* is a native of Europe, particularly of Spain. It differs but little in general characters from the former species; there are two varieties of it.

TEETH, in the Animal Kingdom, are those hard organs situated in the mouth, by which food is seized by many animals and masticated by others. In the Fishes and Reptiles the teeth are organs of prehension only, but in most of the *Mammalia* they serve both for prehension and mastication. The characters of the teeth of the various classes and families of animals are given with the descriptions of the animals in this work. We shall here only refer to the general structure of the human tooth, which may be regarded as the type of all dental structures.

The best method of preparing teeth for microscopic examination is to immerse them in dilute hydrochloric acid, till their earthy matter is so far dissolved that thin transparent slices may be cut from them with a knife; or, without softening them in acid, to make thin sections in the vertical and other directions with a fine saw, and to reduce these to the necessary thinness and transparency by filing them, and polishing them on a hard and smooth whetstone. For general examination, lenses magnifying about 50 diameters are sufficient.

In such a vertical section of a tooth three distinct substances are seen, namely, the dentine or ivory (*fig. 1, a a*), which forms the greater mass, and, as it were, the mould of the tooth, and which contains the pulp cavity (*b*); the enamel (*c c*), by which the crown or exposed part of the tooth is covered; and the bone, cement, or crusta petrosa (*d d*), which forms a thin layer around the fang, except at that part at which the vessels enter the pulp, and is continued in a finer and scarcely perceptible layer over the enamel.

The bone, or cement, has in each animal a minute structure similar to that of which the bones of its skeleton are composed. In man it consists of a basis of homogeneous substance, a compound of cartilage and earthy matter, in which there are minute cavities (*fig. 2*) with delicate branched canals leading from one to the other. On the walls of these canals and cells the earthy matter is deposited more thickly than in the intermediate spaces, so that when examined by transmitted light they appear black or dark gray. The cavities, or bone-corpuscles, in man are round and oval, and flattened; most of them are between $\frac{1}{1000}$ th and $\frac{1}{2000}$ th of an inch in length, and about one-third as much in breadth and one-sixth as much in thickness. They have somewhat jagged edges, from all parts of which there proceed the fine branching canals, to which the name of calcigerous has been given, and which traverse the homogeneous basis of the bone, and communicate irregularly with one another. The diameter of these canals at their largest parts is not more than $\frac{1}{1000}$ th of an inch;

that of their smaller branches is between $\frac{1}{4000}$ th and $\frac{1}{8000}$ th of an inch. Their general direction is towards the axis of the tooth, around which the corpuscles are arranged in concentric circles.

The enamel is composed of solid prisms, or fibres (*fig. 3, a a*), about $\frac{1}{1000}$ th of an inch thick, set side by side and upright upon the ivory of the crown of the tooth (*b*). One end of each prism is fixed in a little depression on the rough outer surface of the ivory; the other, which is somewhat larger, is turned towards the masticating surface of the tooth in the direction in which the chief external pressure is to be resisted. The course of the prisms is more or less wavy, their curves being for the most part parallel (*fig. 4*), but sometimes opposed. Most of them extend from the ivory to the surface of the tooth; and where they do not, small complementary prisms fill up like wedges the vacant spaces.

Fig. 3.

Fig. 4.

Small collection of enamel-fibres.

View of the arrangement of the enamel-fibres on the crown of an incisor tooth.

In the perfect state the enamel contains so small a quantity of animal matter, that it cannot be demonstrated to the sight, and the prisms are inseparably consolidated; but in young teeth it is soft, and may be broken up into its elementary parts. In the early state also it exhibits portions of a membranous animal substance, consisting of the cells in which each of its prisms was formed; for, as will be presently shown, the earthy matter is deposited in what might be called a set of moulds formed by the primary cells of the enamel membrane, and, as it accumulates, the membrane of the cell is so nearly removed, that in the perfect tooth no portion of it can be discerned. Its former existence however seems to be indicated by fine close-set transverse striæ upon each prism of the enamel.

Fig. 5.

1, longitudinal section of a canine tooth, showing the three tissues: *a*, the dentine or ivory; *b*, the enamel; *c*, the cement or dental bone.

2, dental tubes as seen by a low power.

3, a longitudinal section of dentine, showing a dentinal tube dilated, and sending off anastomosing branches.

4, longitudinal section of dentine, highly magnified: *a*, the dentinal tubes; *b*, granular intertubular structure.

5, transverse section of dentine: *a*, the tubes, showing their parietes and area; *b*, the intertubular tissue.

The dentine is made up of two distinct parts: first, dentinal tubes; secondly, intertubular tissue. The tubes have distinct parietes, equal in thickness to their calibre. In some instances they appear to contain a minute granular matter, but in many, perhaps in the majority of cases, they are perfectly free from solid contents. If a vertical section, passing through the pulp-cavity, be taken for examination, the dentinal tubes may be traced from their commencement on the surface of the pulp-

Fig. 1.

Magnified section of a bicuspid tooth.

Fig. 2.

Microscopic view of bone-corpuscles and calcigerous canals.

cavity, to their termination at the junction of the cement, and the dentine on the enamel of the latter, or they may be seen passing into these external structures. The tubuli commence at a right angle with the surface of the pulp-cavity, and proceed outwards towards the surface of the tooth, giving out in their way numerous small branches, which, meeting with other similar branches from neighbouring tubes, anastomose with them, or meeting with simple cells in the intertubular tissue, there terminate. Towards the surface of the dentine it is not uncommon to see a tube alter its course, and by joining another, form a loop. The tubes all commence in the pulp-cavity, and pass outwards towards the surface of the dentine. Their course, as regards each other, is divergent, so that the proportion of the intertubular tissue increases relatively as their distance from the pulp-cavity is greater or less. This preponderance of the intertubular over the tubular tissue near the periphery of the tooth is however in a considerable degree lessened by the more frequent branching of the tubes, and by the occurrence of cells near the surface of the dentine. If a single tube be traced through its whole extent, it will be found to make two undulations; and in addition to these, which are called the primary curves, a number of smaller undulations. In examining this structure a thin section may be taken from the fang, and, with the aid of the microscope, viewed by transmitted light. A tube will then appear as a very definite dark line pursuing its tortuous but definite course towards the surface, giving out numerous minute branches on its way, and at last dividing into two terminal branches, which end either by passing into a cell of the intertubular tissue, or by anastomosis with a collateral tube, or by passing into the cement. If a section of the dentine and enamel be taken, then the tubes will be seen to give out comparatively few branches till they come near to the latter, when they divide and anastomose freely, and some few terminal branches may be traced entering the enamel. It is by no means uncommon for a tube in its course to suddenly dilate and give out branches from the dilatation, then again contract, and pursue its original course. In such a case the dilatation forms a cell in every way similar to the bone-cell. The point of the greatest diameter of the dental tubes is at their commencement on the walls of the pulp-cavity, though in their course previous to the division of the trunk into two terminal branches they suffer but little loss in calibre. In tracing this structure in the teeth of various animals, we find every form of branching; sometimes the branches are few, in others extremely numerous; in some instances they are given out from one side of the tube only, in others from each side; but whatever the modification in the number or form of the branching given out, the primary tube always commences by an open extremity on the walls of the pulp-cavity, or upon the walls of a canal for a blood-vessel; and the direction taken by the tubes is invariably towards the periphery of the tooth, always anastomosing in their way by the numerous branches. In the temporary, and not unfrequently in the permanent teeth, the tubes, instead of presenting an uninterrupted line, present on their surface numerous indentations, just as though they were composed of a series of hollow beads, which were united and made to communicate with each other.

Fig. 7.

Fig. 6.

Views of the tubules of dentines.

The second part composing the dentine is the intertubular tissue, which occupies the spaces between the tubuli, everywhere surrounding and investing them, and thereby contributing greatly in rendering the whole dentine a solid dense mass, the area of the tubes and cells being the only hollow portion. In a favourable specimen of this tissue Mr. Tomes observed that it was composed of very minute granules, united to each other on all sides, thus forming a solid mass, of which, in character of formation, oolite would give a coarse illustration. The granularity is best seen near the external surfaces of perfect dentine, or in the tissue when developing. In the intertubular tissue, hemispherical or elliptical cells are found, especially near the surface of the dentine of the fang, where they form a layer joining the cement.

A separate organ is provided for the formation of each of these three constituent parts of the tooth, though, when they are perfected, they contain no vascular tissue but the pulp within the pulp-cavity; and it is doubtful whether, in the human subject, fresh material is ever

formed from this after the tooth has attained its complete development. The first appearance of the pulp of each tooth is in the form of a minute process or papilla rising from the bottom of a groove in the mucous membrane of the mouth behind the edge of the jaw. In course of time, as the borders of the groove grow around it, the papilla seems to sink into the mucous membrane; and it now appears as if rising from the base of a follicle, or of a flask-like depression, in the edge of the jaw. And lastly, processes of membrane, or opercula, grow from the sides of the mouth of the follicle, and as they approach each other and adhere by their mutually opposed edges, they gradually close it, and convert it into a capsule or sac, to the base of which the first-formed papilla is affixed. In the first-appearing tooth the papillary state may be seen in the human embryo an inch in length: the capsular stage is completed at about the fifteenth week of embryonic life.

These three stages of the formative organs of the tooth, namely, the papillary, the follicular, and the capsular, being completed, the substances of the tooth itself begin to be produced. The dentine is developed from the papilla, which gradually assumes the form and relations of the proper tooth-pulp; the enamel, from a special organ developed at that part of the capsule which is opposite to the papilla; and the bone probably from the interior of the capsule itself. The composition of the enamel and osseous portions of the teeth differs. The following analyses are given by Von Bihra:—

	Molar tooth of a woman aged 25 years.		Molar tooth of an adult male.	
	Enamel.	Osseous portion.	Enamel.	Osseous portion.
Phosphate of Lime, with a little Fluoride of Calcium	81.63	67.54	89.82	66.72
Carbonate of Lime	8.88	7.97	4.37	3.36
Phosphate of Magnesia	2.55	2.49	1.34	1.08
Soluble Salts	0.97	1.00	0.88	0.83
Cartilage	5.97	20.42	3.39	27.61
Fat	a trace	0.53	0.20	0.40

The osseous portion includes the dentine and cement.

TEETHING. [DENTITION.]

TEFFLUS. [CARABUS.]

TEIDÆ, a family of Saurian Reptiles. [SAURIA]. The following is a synopsis of the genera:—

I. Throat with two cross folds, with larger 6-sided scales between.

A. Ventral shields small, long, smooth. Tongue contractile.

1. *Teius*.—Toes 5-5. Femoral pores distinct. Two species.
2. *Callopistes*.—Femoral pores none. Toes 5-5. One species.

B. Ventral shields broad, smooth.

- * Tongue elongate, sheathed at the base. Teeth compressed.
- 3. *Ameiva*.—Toes 5-5. Teeth 3-lobed. Six species.

** Tongue not sheathed, free at the base.

4. *Cnemidophorus*.—Teeth compressed longitudinally, 3 lobed. Toes 5-5. Six species.
5. *Dicrodon*.—Teeth compressed transversely, bifid. Toes 5-5. One species.
6. *Acrantus*.—Teeth compressed transversely, bifid. Toes 5-4. One species.

II. Throat with a collar of large shields.

a. Collar and ventral shields keeled. Tail round.

7. *Acanthopyga*.—Scales of back large, of sides granular. One species.
8. *Centropyx*.—Scales of back and sides moderate, in many series. One species.
- b. Collar and ventral shields smooth, elongate. Tail round.
9. *Emmilia*.—Scales of back rhombic, keeled, equal. One species.
- c. Collar and ventral shields smooth, elongate. Tail compressed.
10. *Crocodylus*.—Scales of back equal, similar. One species.
11. *Custa*.—Scales of back unequal. Throat with a collar of large scales. One species.
12. *Ada*.—Scales of back unequal. Throat with two plaits. One species.

This family is well-illustrated by the *Teius Teguxin* of the British Museum Catalogue. It is the *Lacerta Teguxin*, Linn.; *Seps marmoratus*, Laurenti; *Lacerta Monitor*, Latr.; *Tupinambis Monitor*, Daud.; *Monitor Merianæ*, De Blainville, Van Hasselt and Kuhl, &c.; *Tejus Monitor*, Merr., &c.; *Monitor Teguxin*, Fitzinger; *Podinema Teguxin*, Wagl.; *Wiegmanii*, *Teguxin Monitor*, Gray; *Monitor Teguxin*, Eichw.; *Tejus Teguxin*, Schinz.; Le Grand Sauvage de l'Amérique, Cuv.; Variegated Lizard, Shaw; Great American Safford, Griffith's Cuvier.

The warm countries of America are the native places of the *Teidæ*, which arrive at a considerable size, often measuring as much as 4 or 5 feet in length. Messrs. Duméril and Bihra state that they ordinarily inhabit the fields and the borders of woods, although they never climb trees; but they also appear to frequent sandy, and consequently arid tracts, where they are said to excavate burrows, in

which they lay themselves up for the winter. When, in their flight to avoid pursuit, they come upon a lake, pond, or river, they plunge in, according to D'Azara, to escape from the danger which menaces them, and do not leave the water till all fear of danger is past. These Lizards, observe Messrs. Duméril and Bibron, have not, indeed, webbed feet; but their long and slightly compressed tail becomes, without doubt, under such circumstances, a sort of oar, of which they well avail themselves. D'Azara states that they feed on fruits and insects, and that they also eat serpents, toads, young chicks, and eggs. He also relates that they are fond of honey; and that in order to procure it without fear of the bees, they come forward at intervals, and, as they run away each time, give the hive a blow with their tail, till by repeated attacks they weary out the industrious insects, and drive them from their home.

Variegated Lizard (*Teius Tegulxin*).

Head of Variegated Lizard.

TEIUS. [TEIDÆ.]
TELEOSAURUS. [CROCODYLIDÆ.]
TELESCOPIUM. [ENTOMOSTOMATA.]
TELLINA. [CONCHACEA.]
TELLINIDÆ. [CONCHACEA.]
TELLUR-BISMUTH. [TELLURIUM.]

TELLURIUM, a Metal which was discovered in 1782 by Müller of Reichenstein, but its properties were more minutely examined by Klaproth sixteen years afterwards, and he gave it the name it now bears.

Native Tellurium is found crystallised and massive. Primary form a rhomboid, occurring in minute 6-sided prisms, the terminal edges of which are usually replaced. Cleavage parallel to the faces of the prism. Fracture indistinct. Hardness: scratches sulphate of lime, and is scratched by the carbonate. Easily frangible. Colour tin-white or steel-gray. Lustre metallic. Specific gravity 5.7 to 6.115. Before the blow-pipe it is very fusible, and burns with a greenish flame, and is volatilised in a white vapour. It is soluble in hydrochloric acid.

A massive variety is granular. Colour splendid, tin-white. Lustre metallic. Opaque. Specific gravity 6.115. It occurs in Transylvania, and, according to Klaproth's analysis, gives—

Tellurium	92.55
Iron	7.20
Gold	0.25
	—100

Graphic Tellurium—Auro-Argentiferous Tellurium—occurs crystallised. Primary form a right rhombic prism; occurs in attached flattened crystals, which are generally minute. Fracture uneven. Hardness: scratches talc, and is scratched by calcareous spar. It is brittle. Colour steel-gray. Lustre metallic. Opaque. Specific gravity 5.723. Before the blow-pipe it readily fuses into a globule, and is reduced to a metallic button of a bright yellow-colour. Soluble in nitric acid, except a yellow metallic residue. It is found accompanying gold in narrow veins traversing porphyry at Offenbanya, and

also at Nagyag, in Transylvania. It consists of tellurium, gold, silver, and lead.

Berzelius found also a little sulphur, arsenic, antimony, iron, and copper.

Yellow Tellurium occurs in imbedded crystalline laminae. Primary form a right rhombic prism. Traces of cleavage. Fracture uneven. Hardness: scratches gypsum, and is scratched by calcareous spar. Rather brittle. Colour silvery-white, inclining to brass-yellow. Lustre metallic. Opaque. Specific gravity 10.678. By the blow-pipe it melts into a metallic globule. It is partly soluble in nitric acid. It is found at Nagyag in Transylvania, and in the Altai Mountains in Siberia. According to Klaproth, it contains tellurium, gold, lead, silver, and sulphur.

Black Tellurium occurs crystallised, and in imbedded foliated masses. Primary form a square prism. Cleavage parallel to the terminal plane, in thin flexible laminae. Fracture indistinct. Hardness: scratches talc, and is scratched by gypsum. Colour dark lead-gray. Lustre metallic. Opaque. Specific gravity 7.085. Before the blow-pipe is fusible on charcoal, and covers it with oxide of lead; reducible into a gray metallic globule, which eventually leaves a button of gold. It is found at Nagyag and Offenbanya in Transylvania, and contains, according to Klaproth—tellurium, lead, gold, silver, copper, and sulphur.

Bismuthic Tellurium—Tellur-Bismuth; Telluret of Bismuth—occurs crystallised in small 6-sided prisms. Cleavage parallel to the base of the prism. Fracture indistinct. Hardness: scratches calcareous spar, and is scratched by fluor-spar. Colour steel-gray or zinc-white. Lustre metallic. Specific gravity 7.82. It is fusible by the blow-pipe, and disengages the odour of selenium. Acted on by nitric acid, and the solution is precipitated by water. It is found in Norway, and contains—

Tellurium	34.6
Bismuth	60.0
Sulphur and traces of Selenium	4.8
	—99.4

TELOPHONUS (Swainson), a genus of Birds. [LANIADÆ.] The character of the bill is seen in the accompanying figure.

Bill of *Telophonus leucogrammicus*.

TEMIA (Le Vaillant), a genus of Perching Birds, which, Cuvier observes, M. Vieillot has changed into *Crypsirina*, and Dr. Horsfield into *Threnotrix*, whilst M. Temminck arranges them under *Glaucopsis*.

Bill of *Crypsirina*. (Swainson.)

Mr. Swainson thus characterises *Crypsirina*:—Bill shorter than the head, much compressed; the culmen considerably arched, and curved from the base. Nostrils small, basal, concealed by incumbent feathers, which are either soft or setaceous. Wings short, much rounded; the primaries hardly longer than the secondaries. Tail feathers broad and obtuse. Feet moderate, arboreal. The middle toe and claw

Threnotrix Temia. (Horsfield.)

short, but as long as the tarsus; lateral toes unequal; hind toe and claw shorter than the tarsus. It is a native of India.

C. vagabunda (*vagabunda*) and *C. Temia* are among the species given as examples.

The first of these is the *Pica vagabunda* of Gould ('Century of Birds from the Himalaya Mountains'), a representation of which we subjoin.

Pica vagabunda. (Gould.)

Dr. Horsfield, who gives *Corvus varians* as the synonym of his *Phrenotrix Temia* (the Chekitat, or Bentoot, of the Javanese), states that although not a rare bird in Java, his *Phrenotrix* is by no means familiar, and never approaches the villages and habitations like many others. ('Zoological Researches in Java.') A figure of this bird is given in the preceding page.

TEMNOLEURUS. [ECHINODERMATA.]

TEMNURUS. [TROGONIDÆ.]

TEMPERATURE OF THE EARTH. [GEOLOGY.]

TEMPERATURE OF PLANTS. [HEAT, VEGETABLE.]

TENCH. [TINCA.]

TENDON, or **Sinew**, is the tough white and shining tissue by which muscles are attached to the bones or other parts which it is their office to move. The name of Tendons however is generally applied only to those which are thick and rounded, and which serve for the attachment of the long round muscles, such as those of the biceps muscle on the front of the upper arm: those which are broad and flat, and which serve for the attachment of the membranous muscles, are commonly called **Aponeuroses**. But whatever be the external form of a tendon, its intimate construction is the same, being chiefly composed of the same fibrous or tendinous tissue of which a large class of organs, including the ligaments, fasciæ, periosteum, and several others, consist. [AREOLAR TISSUE; MUSCLE.]

At that end of a tendon which is affixed to a muscle each primitive fibre or fasciculus of the latter terminates in an abruptly-rounded extremity, which is embraced by a fasciculus of the filaments of the tendon, expanding and inclosing it in a sheath, or in a manner which may be coarsely represented by placing the end of the fore finger of one hand within a circle formed by the ends of all the fingers of the other hand. The larger bundles of cellular and fibrous tissue in the tendon are also continuous with the cellular tissue which is placed between the secondary fasciculi of the muscle.

At their opposite extremities the tendons are usually affixed to bones. Their fibres are intermixed and firmly united with those of the periosteum, and often pass into the very substance of the bone.

Although the chief and proper office of Tendons is to serve as media for the action of muscles, yet many of them fulfil other purposes in the economy. Thus the **Aponeuroses** of the abdominal muscles form a great part of the walls of the abdomen, and, by their toughness, support and protect the organs within its cavity; the

Tendons of the muscles of the fingers add strength to each joint over which they pass; and many, in other parts, are arranged so as to act like ligaments.

TENDRAC. [TENREC.]

TENDRILS, or *Cirrhii*, are those elongated and filamentous organs of Plants which possess a power of twisting in one direction or another, and by which the plants on which they grow are enabled to embrace other plants, and thus to elevate themselves. Tendrils are only found on those plants which are too weak in the stem to enable them to grow erect. In most cases the tendrils are only forms of the petiole; for although they may occur on the parts of flowers, yet the flowers must be regarded as metamorphoses of the leaf. Tendrils are distinguished according to the parts of the leaf from which they grow. When the tendril consists of the elongated petiole of a compound leaf, it is called a *Cirrhus Petiolaris*, as in the common pea. When, as in *Smilax horrida*, it branches off on each side at the base of the lamina into a twisting branch, it is called a *Cirrhus Peduncularis*. When it is extended from the point of a single leaf, as in the *Gloriosa superba*, it is a *Cirrhus Foliaris*; and when it occurs in the petals of a flower, as in *Strophanthus*, it is called *Cirrhus Corollaris*. Those tendrils which are in connection with the stem alone, as those of the Passion-Flowers and Vines, are called *Capreoli*. The type of these organs however is the same in all cases. (Bischoff, *Wörterbuch der beschreibenden Botanik*.)

TENGYRA. [SCOLIADÆ.]

TENNANTITE, a variety of Gray Copper-Ore, so named in honour of Smithson Tennant, a distinguished chemist. It occurs in attached crystals, which are usually small. It is found only in Cornwall, and has thereto been found in several copper-mines.

TENORITE. [COPPER.]

TENREC, the common name of a species of *Centetes*, Ill.; *Centetes*, Desm.; *Setiger*, Geoff. The Tenrecs may be considered—indeed they have been considered by most zoologists—as Hedgehogs without the power of rolling themselves up into a ball. They were not included in the genus *Erinaceus* of Linnæus, as he left it, in his last edition of the 'Systema Naturæ' (the 12th), but in the 13th (Gmelin's) all the known species were included under that genus. They have no tail, are nocturnal for the most part in their habits, feed on insects, lie dormant during a considerable portion of the year, and that during the hot season, and have the skin beset with spines, or spine-like bristles.

Dental Formula:—Incisors, $\frac{6}{6}$; Canines, $\frac{1-1}{1-1}$; Molars, $\frac{6-6}{6-6} = 40$.

Teeth of *Tenrec*, one-third larger than the natural size. (F. Cuvier.)

The situation assigned by Cuvier to the Tenrecs is between the Hedgehogs (*Erinaceus*, Linn.) and *Cladobates*.

C. caudatus (Ill.) is the largest of the species, exceeding our Hedgehog in size. It is covered above with long flexible spines, except on the vertex and occiput, and has no coloured bands; the under part of the body is clothed with hairs or bristles only, which are yellowish, mixed with some longer black ones.

Centetes caudatus.

C. setosus, Ill. (the Tondrac of Buffon and Zimmerman), is less than the former, and the spines are short and rigid.

Tondrac (*Centetes setosus*).

C. semispinosus is still less, and hardly so large as a common mole. Its body is clothed with a mixture of spines and bristles, and is banded longitudinally with yellow and black.

Striped Tenrec (*Centetes semispinosus*).

TENTACULITES (Schlottheim), a genus of small annulated pointed shells, fossil in the Silurian strata.

TENTHREDO, a genus of Hymenopterous Insects, of the section *Terebrantia*. The genus *Tenthredo* of Linnæus is in modern systems regarded as constituting a family, to which the name *Securifera* has been applied by Latreille, and *Tenthredinidae* by Leach.

Latreille restricts the generic term *Tenthredo* to those species which have nine joints to the antennæ, and in which these organs are not distinctly thickened at the apex. Their larvæ have from eighteen to twenty-two feet. The genus *Tenthredo* is however still further restricted by many other authors, and it is especially to Dr. Leach ('Zoological Miscellany,' vol. lii.) that we are indebted for pointing out distinguishing characters for the subdivisions of the very extensive Linnæan genus. By this author the *Tenthredinidae* are divided chiefly according to the structure of the antennæ, and the cells inclosed by the nervures of the wings. The first section, according to Dr. Leach, contains those species which have the antennæ short and clubbed at the extremity and the third joint long; the superior wings with two marginal and three submarginal cells. It includes the genera *Cimbex*, *Trichiosoma*, *Clavellaria*, *Zarea*, *Abia*, &c.

The species of the second section have the antennæ of moderate length, filiform, and composed of three joints; the last joint long, slightly thickened at the extremity, and in the males ciliated, and sometimes forked. It contains the genera *Hylotoma* and *Schizocerus*. The characters of the third section are:—Antennæ short, with nine or ten joints, increasing in thickness in the middle, but ending in a point; the third joint longer than the fourth; body short and increasing in thickness towards the apex. Genera: *Messa*, *Selandria*, and *Fenusia*.

Section 4.—Antennæ composed of nine joints, moderately long; body moderately long; upper wings with two marginal cells. To this section belongs the genus *Tenthredo* as at present restricted; it is distinguished by the upper wings having four submarginal cells, and the antennæ with the third and fourth joints of equal length. The genus *Allantus* differs only from *Tenthredo* in having the third joint of the antennæ longer than the fourth. The *Allantus scrophulariæ* is a very common species in this country, and is found on the *Scrophulariæ*, on the leaves of which its larvæ feed. The perfect insect somewhat resembles a wasp, but is of a rather more slender form; it is black, and has the body adorned with yellow rings; the legs (with the exception of the thighs) and antennæ are also yellow. The larva, which is provided with twenty-two feet, is white and has black dots, and the head is black. When touched it rolls itself up in a spiral manner, as indeed do the larvæ of other *Tenthredinidae*.

Section 5.—Superior wings with but one marginal cell; body short, narrower at the extremity in the males; antennæ simple, nine-jointed, slightly ciliated, increasing in thickness in the middle, and decreasing at the extremity. This section contains the genera *Cræsus*, *Nematus*, and *Cladius*, examples of each of which are found in this country.

Section 6.—Antenna with numerous joints; body rather depressed; wings with two marginal and four submarginal cells. British genera *Tarpa*, *Lyda*, and *Lophyrus*. The larvæ of the species of *Lophyrus* live in society, more particularly on the pines, and are said to be very injurious to the young plants. The species of this genus are very rare in England. The antennæ are serrated in females, and in the males they are provided with a double series of denticulations.

TENUIPEDES. [MALACOLOG.]

TENUIROSTRES, a family of Birds belonging to the order *Insectores*. Cuvier makes the *Tenuirostres* the fourth family of his *Passeraux*, placing it between the *Coniostres* and the *Syndactyles*, and comprising under it the genera *Sitta*, Linn. (with the sub-genera *Xenops*, Ill.; *Anabates*, Temm.; and *Synallaxis*, Vieill.); *Certhia*, Linn. (with the sub-genera *Certhia*, Cuv.; *Dendrocolaptes*, Herm.; *Tichodroma*, Ill.; *Nectarinia*, Ill.; *Dicaeum*, Cuv.; *Melithreptus*, Vieill.; *Cinnyris*, Cuv.; and *Arachnathera*, Temm.); *Trochilus*, Linn. (dividing the genus into the Humming-Birds properly so called, or *Colibris Trochilus*, Lacép.; and the Oiseaux Mouches, or Fly-Birds, *Orthorhynchus*, Lacép.); *Upupa*, Linn. (with the sub-genera *Fregilus*, Cuv.; the Hoopoes properly so called; *Upupa*; *Promerops*; and *Epimachus*).

Mr. Swainson includes the following families under this tribe:—*Meliphagidae*; *Cinnyridae*; *Trochilidae* (Humming-Birds); *Promeropidae* (Hoopoes); and *Paradisidae* (BIRDS OF PARADISE).

The *Tenuirostres* are placed by this author between the *Scansores* and the *Fissirostres*.

M. Lesson makes the tribe *Tenuirostres* (which he arranges between the *Latirostres* and the *Syndactyles*) consist of the following families and genera:—

1. *Promeropidae*.

Genera:—*Upupa*; *Promerops*.

2. *Certhiidae*.

Genera:—*Certhia*; *Tichodroma*; *Dendrocolaptes*; *Climacteris*; *Furnarius*; *Cureba*; *Dicaeum*.

3. *Philetonidae*.

Genera:—*Drepanis*; *Cinnyris*; *Pomatorhinus*; *Prinia*; *Orthotomus*; *Myzomela*; *Myzantha*; *Anthochaera*; *Tropidorkhynchus*; *Mellisuga*.

4. *Trochilidae*.

Genera:—*Polytmus*, Briss.; *Ornismya*, Less.

In Mr. G. R. Gray's 'List of the Genera of Birds' (2nd edit, 1841), the *Tenuirostres* stand as the second tribe of *Insectores*, between the *Fissirostres* and the *Dentirostres*, and comprise the following families, sub-families, and genera:—

1. *Upupidae*. 2. *Nectarinidae*. [CINNYRIDÆ.] 3. *Trochilidae*. 4. *Meliphagidae*.

TEPHRODORNIS (Swainson), a genus of Drongo Shrikes, *Dicrurina*. [LANTIDÆ.] The accompanying cut represents the bill in this genus.

Bill of *Tephrodornis*. (Swainson.)

TEPHROITE. [TROOSTITE.]

TEPHROSIA (from *tephros*, ash-coloured), the name of a genus of Plants belonging to the Papilionaceous division of the order *Leguminosae*. The genus consists of shrubs or herbs, with usually unequally pinnated leaves, and lanceolate or subulate stipules distinct from the petiole. The flowers are white or purplish, arranged in racemes which are mostly axillary; the calyx is without bracts, 5-toothed, nearly equal; vexillum of corolla large, silky outside, and reflexed in a spreading manner; wings adherent to the keel; stamens separate or united in one or two parcels; legume mostly sessile, linear, compressed, many-seeded, with the valves flat; seeds compressed. This genus at present includes 84 species, but it is probable that a more accurate investigation will result in making several genera of the present one. The American and Asiatic species are in some measure distinguished by their properties. In the former a narcotic poison is more frequently secreted; in the latter a colouring matter.

T. toxicaria, the Poison Tephrosia, is a half-shrubby erect plant, with 18 to 20 pairs of oblong-lanceolate obtuse leaflets, pubescent on the upper surface, silky beneath; legumes linear, velvety, mucronate. This plant is a native of the West Indies and of Guyana, and is said by Tussac to have been first brought from Africa. The whole plant affords a narcotic poison, and if the leaves are taken and pounded, and then thrown into water where there are fish, they become intoxicated, and losing all power over their muscles, they float about as if dead, and may be easily caught. If placed in fresh water, or the fresh water be allowed to come in contact with them as in a stream, the fish soon recover: it is however generally fatal to the smaller fish.

T. Virginiana is found in woods, on dry and sandy soils, in North America from Canada to Florida. It is considered in America a powerful vermifuge. Several other species of *Tephrosia* are found in North America.

T. emarginata, a native of South America, possesses the same properties as the *T. toxicaria*, and is also used for the purpose of poisoning fish.

T. tinctoria, the Ceylon Indigo, is a shrubby glabrous plant with 5 pairs of leaflets, silky and villous beneath; flowers purple or flesh-coloured, seated on axillary peduncles; straight pendulous legumes. This plant is a native of Ceylon, where it is called Anil. Its tissue yields a blue colouring-matter, which has the same properties as the indigo, and is used in Ceylon for the same purposes. There are other plants used in Ceylon for dyeing also called Anil.

T. piscatoria, the Fisher's Tephrosia, contains the narcotic principle of the genus, and is used in the East Indies for the same purposes as *T. toxicaria* is in the West Indies.

T. Apollinea is shrubby, and covered with a close pubescence; the leaflets are silky beneath, and in 2 or 3 pairs; the legume is 6- or 7-seeded, and rather pubescent. It is a native of Egypt, and yields a blue colouring-matter, which is used in dyeing.

T. Senna, Buga Senna, is a glabrous shrub, with leaves having 6 pairs of leaflets, and the legumes and calyxes covered with pubescence. It grows on the banks of the river Cauca, near Buga, in Popayan. Its leaves have a purgative quality like senna, and are used by the natives for the same purposes as that plant is used.

TERATICHTHYS, a Fossil Fish. [FISH.]

TEREBELLA. [TUBICOLIDÆ.]

TEREBELLARIA, a genus of *Polypnaria*, included by De Blainville in the family of *Milleporæ*.

TEREBELLUM, a genus of *Mollusca*, placed by Cuvier among his Pectinibranchiate Gastropoda, between *Orula* and *Voluta*; by De Blainville among his *Angustomata*, between *Conus* and *Oliva*; and by Rang between *Mitra* and *Ancillaria*.

The fossil *Terebellum convolutum* is the type of Montfort's genus *Scapha*.

T. subulatum, a native of the East Indies, may be taken as an example of the recent species, and *T. convolutum* of the fossil forms.

Terebellum convolutum. (Genus *Scapha* of Montfort.)

The fossil species appear to belong to the tertiary formation, Eocene period of Lyell (Grignon, &c.).

TEREBINTACEÆ, a natural order of Dicotyledonous Plants constituted by Jussieu, and adopted by De Candolle, Arnott, Don, and other writers on systematic botany. Brown has however divided it into five orders. [ANACARDIACEÆ; BURSERACEÆ; CONNARACEÆ; SPONDIACEÆ; AMYRIDACEÆ.]

TEREBRA. [ENTOMOSTOMATA.]

TEREBRALLIA. [ENTOMOSTOMATA.]

TEREBRATULA. [BRACHIOPODA.]

TEREDINA, a genus of *Mollusca* belonging to the family *Tubicolæ* of Lamarck, and to the *Adeimacea* of De Blainville.

This genus is fossil only. Lamarck places it between *Septaria* and *Teredo*; Cuvier between *Fistulana* and *Clavagella*.

Mr. Swainson arranges it in his family *Pholidae*, and makes it a sub-genus of *Teredo*.

Dr. J. E. Gray places the *Teredina* among the *Pholidae*, between *Jouannetia* and *Teredo*. [FISTULANA; CLAVAGELLA.]

Teredina personata. (Courtagnon, &c.).

a, tube with valves; b, the other termination of the tube; c, accessory valve; d, valves with accessory valve in its place. (G. B. Sowerby.)

TEREDO. [PHOLIDIDÆ.]

TERIGIPES. [NUMIDIANCHIATA.]

TERMES. [TERMITINA.]

TERMINALIA (from 'terminus'), is the name of a genus of Plants belonging to the natural order *Combretaceæ*. The species of this genus consist of trees and shrubs, with alternate leaves, which are usually crowded together at the ends of the branches. The flowers are

Terebellum subulatum.

destitute of petals, and are disposed in spikes, which are racemose and panicked; in the lower part of the spikes they contain both stamens and pistils, but in the upper part they contain only stamens; the limb of the calyx is campanulate, 5-cleft, with acute lobes; the stamens are 10 in number, arranged in two series, and are longer than the calyx; the ovary contains two ovules; the style is acute, and the fruit is drupaceous, containing only one seed. All the species are inhabitants of the tropical parts of Asia and America. They are numerous, and many of them are used in medicine and the arts.

T. angustifolia. The leaves are linear-lanceolate, very thin at both ends, pubescent beneath; the petioles are also pubescent, and have two glands at their apex. This tree is a native of the East Indies, and was formerly called *Terminalia Benzoin*, as it yields on tapping a gum-resin very similar to benzoin, and possessing the same properties.

T. vernix is a native of the Moluccas, and abounds in a resinous juice, which is collected by the inhabitants, and used in the natural state as a varnish. It is also used for the same purpose in China.

T. Calappa has obovate leaves, tapering to the base, pubescent beneath, and glands on the under sides of the midrib. It is originally a native of the East Indies, but has now become naturalised in the West India Islands. Some botanists have described the West India species as distinct from the Asiatic, but there is no good distinctive character. The drupaceous fruit of this tree is about 3 inches long, and contains a large seed, which is eaten, and also yields an oil, in the same manner as the almond. This tree, on account of its thick foliage, is much planted in the tropics for the purpose of forming avenues near houses. The bark and leaves yield a black pigment. Indian ink is manufactured from the juice of this tree.

T. glabrata very much resembles the last, but the leaves are glabrous beneath and small. It is a native of the Society and Friendly Islands.

T. Bellerica is a native of the East Indies, and the fruit is reputed to possess tonic, astringent, and attenuant properties.

T. Chebula is also an East Indian species. It is distinguished from the last by possessing opposite leaves which are pubescent beneath. The fruit of this species is more astringent than the last, and is used for the purposes of dyeing. A durable ink is made by mixing the salts of iron with an infusion of the outer rind of the fruit. Both this species and the last are subject to the attacks of insects producing gall-nuts. These galls possess the astringent principle in abundance, and are also used for dyeing. They are called Cadacay by the Tamuls.

TERMITINÆ, a section of Neuropterous Insects, in which Latreille includes the genera *Mantispa*, *Raphidia*, *Termes*, and *Psocus*. These genera however are usually regarded as constituting three distinct families, and will be here treated as such, commencing with the *Raphidiidæ* of Leach, which contains the two first-mentioned genera. The insects of this family have the antennæ slender and composed of more than 10 joints; the tarsi have from 3 to 5 joints; the wings are nearly equal in size and have numerous nervures inclosing small polygonal cells; the prothorax is long and slender.

Mantispa is at once distinguished by the peculiar structure of the anterior pair of legs, which are large, have the tibia broad and compressed, and provided beneath with spines; the joints of the tarsi are indistinct, and also furnished beneath with spines; the tarsi of the other four legs are distinctly 5-jointed. The antennæ are short, about equal to the head in length, and slender. The prothorax is elongated, slender, and broadest in front. The wings, when at rest, meet over the abdomen.

M. pagana, Fabricius, is rather less than three-quarters of an inch in length, and of a brownish-yellow colour; the wings are transparent, the superior pair have the upper margin yellow. It is found in France and Germany.

In Brazil are species closely allied to *Mantispa*, which differ in having the antennæ as long as the body; the wings are nearly horizontal; the body is depressed and terminated by two little appendices. They form the genus *Hoplophora* of Perty.

Raphidia.—The body is rather slender; the prothorax is long and almost cylindrical; the head broad and somewhat depressed; the eyes prominent; the antennæ are as long as the head and thorax, and composed of about 37 joints. The abdomen is terminated in the female by a long ovipositor. The legs are slender, of moderate length, and the tarsi are 4-jointed.

R. ophiopsis is not an uncommon insect in this country. It is rather more than one-third of an inch in length, and the expanded wings measure two-thirds of an inch; the head and body are black, the antennæ and legs are yellow, and the wings are transparent.

The larva of this insect lives in the bark of trees, and is said to prey upon other insects. It is exceedingly active in its motions, which are somewhat like those of a snake. The body is soft, long, and slender, of a brown colour, striped, and variegated with yellow; the head and prothorax are corneous, and of a black colour. In the pupa all the parts of a perfect insect are distinct, being enveloped in a thin membrane.

Termitidæ.—This family is distinguished by the following characters:—Wings with few transverse nervures, folding horizontally; tarsi 4-jointed; antennæ short and mouldiform; body depressed.

Termes has the head large and rounded, and, besides the ordinary compound eyes, it has three ocelli, or simple eyes, situated on the

upper surface; the antennæ are as long as the head and thorax, inserted in front of the eyes, and composed of about 18 joints. The abdomen is terminated by two small jointed appendages.

The Termites, or White Ants, as they are often called (though they have little affinity with the true Ants), are chiefly confined to the tropics; some few species however extend into the temperate regions. Like the Bees, Wasps, and Ants, which live in society, the Termites are composed of three kinds of individuals—males, females, and what are termed neuters or workers. Their ravages in the warmer parts of the globe are well known. They unite in societies composed each of an immense number of individuals, living in the ground and in trees, and often attacking the wood-work of houses, in which they form innumerable galleries, all of which lead to a central point. In forming these galleries they avoid piercing the surface of the wood-work, and hence it appears sound when the slightest touch is sometimes sufficient to cause it to fall to pieces.

The Termites sometimes erect their domiciles on the ground, in the form of pyramids or cones, sometimes with a roof, and these nests are often very numerous, and resemble the huts of savages.

The larvæ nearly resemble the perfect insect, excepting that they possess no wings. The pupæ have rudimentary wings. The neuters differ from the males and females in possessing no wings, in having the body stouter, the head much longer, and provided with long jaws crossing at the extremity. They are said to defend the nests, and, stationing themselves near the outer surface, they are the first to make their appearance when their habitation is disturbed. They will attack the party molesting them, and bite with considerable strength.

The negroes and Hottentots consider these insects a great delicacy. They are destroyed with quick-lime, or more readily with arsenic, which is thrown into their habitations.

The *Psocidæ* are very small insects, having soft and swollen bodies; the head is very large, nearly trigonal, and provided with three ocelli on the upper surface; the wings when folded meet at an angle above the abdomen, and are sparingly provided with nervures; the antennæ are setaceous, and composed of about 10 joints; the tarsi are short, and usually 2-jointed. They are very active in their motions, and live in the bark of old trees and in dwelling-houses. Nearly 40 species are said to be found in this country.

TERNSTRÖMIACEÆ.

TERNSTRÖMIACEÆ, *Theads*, a natural order of Polypetalous Exogenous Plants. It consists of trees or shrubs with alternate coriaceous leaves, without stipules, mostly undivided, and sometimes with pellucid dots. The flowers are generally white in colour, sometimes pink or red, and are arranged in axillary or terminal peduncles, articulated at the base. The calyx is composed of 5 or 7 sepals, imbricated in æstivation, the innermost the largest; petals 5, 6, or 9, often combined at the base; stamens indefinite, with monadelphous or polyadelphous filaments, and versatilo or aduate anthers; ovary superior; capsule 2-7-celled; seeds few, attached to a central axis, with little or no albumen, and a straight embryo, the cotyledons of which are very large, and often filled with oil. This order includes the *Theaceæ* of Mirbel and the *Camelliæ* of De Candolle. Their closest affinity is with the order *Guttiferæ*, from which they differ in their alternate leaves; in the

Thea Bohea.

1, branch with flowers and leaves; 2, superior ovary with trifid stigma; 3, fruit entire; 4, capsule dehiscent.

parts of their flowers being 5 and its multiples; in the calyx being distinct from the corolla; in their twisted aestivation, and in their thin inadherent cotyledons. They have also relations with *Hypericaceæ* and *Marcgraviaceæ*. The plants of this order are principally inhabitants of Asia and America; one species only is a native of Africa. [THEA; CAMELLIA; COCHLOSPERMUM.]

TERRAPENE, or TERAPIN. [CHELONIA.]

TERRICOLA. [ANNELIDA.]

TERRIER (*Canis familiaris Terrarius*), a variety of the Dog remarkable for the eagerness and courage with which it goes to earth, and attacks all those quadrupeds which come under the gamekeeper's denomination of Vermin, from the Fox to the Rat.

The breed of Terriers recommended in the old times when the huntsman went on foot, was from a Beagle and Mongrel Mastiff, or from any small thick-skinned dog that had courage. Thus the coat and courage were supposed to come from the Cur, and the giving tongue from the Beagle. The time for entering the young terriers at a fox or badger was when their age was ten or twelve months, with an old terrier to lead them on. When entered at a fox, and the old one was taken, the young terriers were set to attack the cubs unassisted, and when they killed them, both young and old terriers were rewarded with the blood and livers fried with cheese, with fox's or badger's grease: at the same time the dogs were shown the beads and skins to encourage them. There were other ceremonies recommended, too cruel to be repeated, and which could have been of little or no service. Honest Dandie Dinmont's mode of entering his Pepper and Mustard generations is as good as can be practised.

A cross of the Terrier with the Bull-Dog for the purposes of badger-baiting, &c., was not one time much in vogue. Of this breed was the celebrated dog Billy, famous for the destruction of rats. He was often turned into a room with 100 of those animals, and he frequently killed every one of them in less than seven minutes.

TERTIARY STRATA, the title given by almost universal consent of geologists to the uppermost great group of strata. Previous to the publication of the 'Essay on the Geology of the Basin of Paris,' by Messrs. Cuvier and Brongniart, in 1810, but little attention had been awakened to this great mass of deposits, though the familiar use of the terms primary and secondary, and the acknowledged dissimilitude between the latest of these strata and modern accumulations from water, in respect of mineral aggregation and organic exuvie, seemed to be propitious to the discovery of a newer type more in harmony with existing nature.

The extent to which, over great tracts in all quarters of the globe, this type has been found to prevail, is exceedingly great: most of the capital cities of Europe are built upon tertiary strata; many of the broadest plains and widest valleys in the New and the Old World are nothing but the dried beds of seas and lakes of the tertiary period: and some considerable mountain ranges bear on their high summits, and still more abundantly on their flanks, portions of the shelly tertiary strata which were uplifted from their original horizontality and subjected to the convulsive movements of which the mountain ranges are the result. In almost every part of the globe strata of this tertiary series prevail, and yield astonishing numbers of shells, corals, *Crustacea*, and other remains of marine, fresh-water, and terrestrial *Invertebrata*, and more locally abundant layers of fishes, and rich deposits of bones of *Mammalia*, &c. Possessing so many attractions, and affording such unusual facilities for study, the tertiary strata of Italy, France, England, Northern Europe, the eastern states of North America, the great tracts of Brazil, Patagonia, &c., have been the theatre of great and laborious investigations, which have brought forward our knowledge of these deposits to at least an equal advance with that of the older strata.

More than this can hardly be said with justice; for though, in consequence of the great similitude between the agencies concerned in producing modern accumulations of sediments and organic exuvie, and those which produced the tertiary strata, the minute history of particular portions of these is almost completely known, their general history is imperfectly comprehended, because the original formation of those strata was performed under as great a variety of local conditions as the accumulations of sands and shells on the actual sea-bed, and because, since their production and elevation from seas or lakes to form dry land, they have, from their surface position and inferior induration, been more subject to superficial waste and destruction than the older, more sheltered, and more consolidated strata. The incompleteness of our knowledge of the general history of the tertiary strata is evident by the incompleteness of the classification which represents that history, and on this point, the only one which it appears necessary here to discuss, we shall offer a few remarks. Among the primary and secondary strata [GEOLOGY] subdivisions corresponding to successive times of production have been found practicable and definable, and traceable over immense areas by means of a combination of mineral, structural, and organic characters. Limestones of certain kinds, as chalk, oolite, magnesian-limestone, accompanied with green, brown, or red arenaceous and argillaceous beds, and holding *Spatangi*, *Apicrinites*, or *Paleonisci*, mark and distinguish cretaceous, oolitic, and magnesian formations and systems of secondary strata corresponding to the carboniferous and other older systems of rocks. This has not been found so practicable in regard to the tertiary strata,

which, though presenting many different sorts of strata, offer in the manner of combination amongst these too many general analogies, and too much of local difference, to be conveniently ranged into formations or systems having more than a local value, by means of mineral and structural characters.

Some assistance towards the desired classification appeared to be furnished by the alternation of marine and fresh-water sediments, as in the Isle of Wight, and in the Basin of Paris, and hence the titles of Upper and Lower Marine, Upper and Lower Freshwater Deposits acquired a considerable application. But the most successful and probably best-founded classification of tertiary strata rests upon a study of their organic contents.

It has been long remarked that in those strata, wherever they occur, the forms of animal and vegetable life make a near approach, even specifically, to living types. By careful examination, a certain number of species have been found in tertiary strata actually identical with or undistinguishable from living objects. The proportion in which these still living species are mixed with now extinct (or believed to be extinct) forms varies, so that in Sicily tertiary beds occur with above 90 per cent. of still living species of shells, but in the basins of London and Paris others are found containing only about 5 per cent.

There are reasons independent of these proportions, which leave no doubt that the strata near London and Paris, which contain only 5 per cent. of living forms, are among the oldest of tertiary beds; while the Sicilian beds, which contain only about 5 per cent. of extinct species, are among the most recent.

Views of this kind generalised lead to a speculation which is strongly confirmed by the general current of geological discovery, that the relative antiquity of tertiary strata may be judged of by the relative proportion of extinct species of shells which are found in them. On this postulate M. Deshayes and Sir Charles Lyell have founded the most prevalent modern classification of tertiary strata, which may be thus briefly sketched:—

Recent Period.

Newer Pleiocene Period, the strata containing not above 10 extinct species in 100.

Older Pleiocene Period, the strata containing about 50 or 60 extinct species in 100.

Melocene Period, the strata containing about 80 extinct species in 100.

Eocene Period, the strata containing about 95 extinct species in 100.

Secondary Period.

(These terms are taken from the Greek *καιρός*, recent, combined with *πλεῖον*, more, *μεῖον*, less, and *ἡώς*, the dawn).

The principle of per centage employed by Sir Charles Lyell in this classification should not be strongly objected to on account of its rigorous numerical results being sometimes found locally inapplicable. It is impossible that this should be otherwise, for the numerical proportions of organic life must always vary in proportion to local conditions as well as to the general succession of physical influences; but that the great cause of the systematic variations of the forms of plants and animals in successive geological periods, whether primary, secondary, or tertiary, is the successive and systematic change of physical circumstances influential on organic life, appears amply proved. There appears no good reason to doubt that the variations of individual organisations, and the numerical proportions of their combinations, are in harmony with and indicative of the successive physical conditions when they lived, and consequently of the successive periods to which these physical conditions belonged. The comparison of individual fossil and living forms is merely one mode, and that not the most general or important, of manifesting the numerical constants of organic life of the several geological periods. By some other less obvious arithmetical processes, the relative analogies of ancient and modern nature may be made to appear numerically, independent of any such specific comparisons, and without limitation of geological age or geographical region. This has been attempted in regard to the Palaeozoic fossils generally, and to the fossils of Devonshire specially, and the result affords remarkable encouragement to the application of rigorous calculations based on exact data representing the numbers of distinctly recognisable forms of different groups of organic remains, whether these be of living or extinct tribes.

We have only further to remark, that the tertiary strata are far more distinctly defined and separated from the uppermost secondary strata than from the recent deposits of water. In fact the most natural classification of tertiary volcanic products, tertiary strata, and tertiary organic remains, is with the living creation. In tertiary strata the phenomena of mineral accumulation seem to be such as are witnessed in daily operation: they contain marine, littoral, and pelagic deposits; estuary and fluvial sediments; lacustrine beds hardly distinguishable from such as are now in progress. In these sediments occur remains of a system of terrestrial and aquatic life as complete (if we except reasoning man) as that now in activity; and if the absence of man, and the animals which seem to be associated with him for his comfort and advantage in the actual creation, be thought a sufficient reason to remove from historic time the account of tertiary deposits, and to justify the adoption of a distinct quaternary or modern period

in geological classifications, it is not the less true that the geological date of the epoch of this period, the line of separation between it and the tertiary eras, is entirely unknown by direct and positive facts, and appears incapable of determination by reasoning on any collateral phenomena at present ascertained.

(Lyell, *Principles of Geology*; De la Beche, *Geological Manual*; Phillips, *Paleozoic Fossils of Devon*.)

TESTACELLUS, the name of a genus of Pulmoniferous *Mollusca*. *T. Maugei* may be given as an example. This form appears to have been first noticed by M. Dugué, in a garden at Dieppe in 1740: but it does not seem to have attracted much attention till M. Mauge, some years since, brought home specimens from the island of Teneriffe. It has also been found in several parts of France, and in Spain, and more recently in a garden at Bristol.

Shell of *Testacellus Maugei*. a, inside; b, outside.

Testacellus Maugei. a, shell in situ. (G. B. Sowerby.)

TESTUDINARIA, a genus of Dictyogenous Plants belonging to the natural order *Dioscoreaceæ*.

T. Elephantipes, the Elephant's-Foot Plant, is well known in our collections of plants from its curious truncate rootstock, looking like an elephant's foot. It is covered with a soft corky bark, which is split so as to give it a rough character. From the top of this thick mass a climbing stem is sent, which bears the leaves and flowers. Like the rest of Dictyogens this stem has not the regular division of the parts of the stem seen in most Exogenous Plants.

TESTUDINATA. [CHELONIA.]

TESTUDO. [CHELONIA.]

TETE. [SENNA.]

TETHIUM. [SPONGIADÆ.]

TETHYS. [NUDIBRANCHIATA.]

TETRABRANCHIATA. [BELEMNITE; BELLEROPHON; CEPHALOPODA; GONATITES; NAUTILIDÆ; OCTOPODA; SEPIADÆ; SPIRULIDÆ; TEUTHIDÆ.]

TETRACAULODON. [MASTODON.]

TETRACERUS. [ANTIOPEÆ.]

TETRACLITA. [CIBRIPIEDIA.]

TETRADYMITE. [BISMUTH.]

TETRADYNAMOUS (from *tétrapes*, four, and *dýnamis*, power), a botanical term employed by Linnæus to indicate the character of those flowers which, possessing six stamens, have two of them shorter than the other four. [CRUCIFERÆ; SYSTEM, SEXUAL.]

TETRAGONA. [ACALEPHÆ.]

TETRAGONIA/CEÆ, *Aizoon*, a natural order of Exogenous Plants. It includes the genera *Tetragonia*, *Aizoon*, *Sesuvium*, and *Miltus*, which are generally placed in the order *Ficoideæ*, or *Mesembryaceæ*. The reason given by Dr. Lindley for this separation is the want of petals in these genera, as he considers that the tendency to produce petals in the *Mesembryaceæ* is of too powerful a nature to admit exception. The relation of these apetalous *Ficoideæ* to *Chenopodiaceæ* is so strong, that Dr. Lindley says "there is no character to distinguish them except their ovary being formed of several carpels."

Tetragonia expansa is a native of New Zealand and Japan, and is used by the natives of those countries as a remedy in those forms of cutaneous disease called scorbatic. The *Aizoon Canariense* and *A. Hispanicum* grow on the sea-coasts of the Canary Isles and Spain, and are amongst the plants which yield soda after burning.

TETRAGONOLEPIS, a genus of Fossil Fishes. [FISH.]

TETRAGONOLOBUS (from *tétrapes*, four, *γωνία*, angle, and *λόβος*, lobe), a genus of Plants belonging to the natural order *Leguminosæ*. It contains herbs with broad leafy stipules, trifoliate leaves, winged petioles, alternate leaflets, and flowers seated on axillary peduncles, furnished with a bract. The calyx is tubular 5-cleft, the wings shorter than the vexillum; the stigma is funnel-shaped and beaked; the legume is cylindrical, furnished with four foliaceous wings, which give it a 4-cornered appearance.

T. purpureus, Purple-Winged Pea, is a pilose plant with decumbent stems, entire obovate leaflets, bracts longer than the calyx, and a glabrous legume, with globose seeds. It is a native of the south of Europe, and has dark purple flowers; a variety is however found with flowers of a dark-yellow colour.

There is also a variety called *T. p. minor*, in which the stem, leaves, and legumes, are much smaller. The unripe legumes are cooked and eaten in the same manner as we eat French beans.

There are four other species of *Tetragonolobus*, all of them inhabitants of Europe.

TETRA'NTHERA, a genus of Plants belonging to the natural order *Lauraceæ*. The flowers are dioecious, some hermaphrodite, involucreted. The calyx 6-parted, the segments nearly equal or wanting. The fertile stamens generally about 9, in the petaloid flower from 12 to 21. The leaves are variable, with pinnate veins.

T. Roxburghii is a variable plant, a native of the mountains of India and China. The fruit is globose, black, and about the size of a pea, yielding a kind of greasy exudation from which the Chinese manufacture candles of a bad quality, and which serves as a basis for salves. This fixed oil is supposed to constitute the principal part of the fruit of *Persea gratissima*, so much esteemed in the West Indies under the name of Avocado Pear.

TETRAO. [TETRAONIDÆ.]

TETRAODON. [TETRODON.]

TETRAOGA'LLUS, a genus of Birds, placed by Mr. G. R. Gray in the sub-family *Lophophorinæ*, of the family *Phasianidæ*.

TETRAO'NIDÆ, a family of Rasorial Birds, to which the Common Grouse belongs.

Linnaeus, in his last edition of the 'Systema Naturæ,' places the genus *Tetrao* at the end of his fifth order, *Gallinæ*, next to the genus *Numida*. The *Gallinæ* come between the *Grallæ* and the *Passeres*; the genus *Struthio* is the last of the order *Grallæ*, and the genus *Columba* the first of the order *Passeres*.

The Linnæan genus *Tetrao* is very extensive, comprising not only the true Grouse, but also the Francolins, Partridges, and Quails.

Cuvier, in his last edition of the 'Règne Animal,' arranges the *Tétrás* (*Tetrao*, Linn.) under his fourth order, *Gallinacées* (*Gallinæ*, Linn.), placing them between the Pheasants (*Phasianus*, Linn.) and the Pigeons (*Columba*, Linn.).

This great genus in the arrangement of Cuvier is more comprehensive even than that of Linnaeus, for it includes the following sub-genera:—1, *Les Coqs de Bruyère* (*Tetrao*, Latb.); 2, the *Lagopèdes*, or Snow Partridges (*Perdix de Neige*); 3, the *Ganga*, or *Attagen* (*Pterocles*, Temm.); 4, the *Partridges* (*Perdix*, Briss.), comprising the *Francolins*, the ordinary *Partridges*, the *Quails*, and the *Colins*, or *Partridges* and *Quails* of America; 5, the *Tridactyls* (*Lacép.*, *Hemipodius*, Temm.), including *Turnix*, (Bonap., *Ortygis*, Ill.), and *Syrphaptiles*, Ill.; 6, the *Tinamous* (*Tinamus*, Lath., *Crypturus*, Ill., *Ynambus*, D'Azara). Of this last sub-genus Cuvier remarks that some, the *Pezus* of Spix, have still a small tail hidden under the feathers of the rump; others, the *Tinamus* of Spix, have no tail at all, and their nostrils are placed a little farther backward; and he adds that one should distinguish *Rhynchotus* of Spix, which has the bill stronger, without any furrow, slightly arched and depressed, with the nostrils pierced towards its base.

Mr. Vigors places the *Tetraonidæ* among the *Rasores*, observing that the groups which form the family are chiefly distinguished in modern systems from those of the *Phasianidæ* by their more simple appearance; by the absence in fact of those ornaments to the plumage, and those naked or carunculated appendages to the cheeks and head, so conspicuous in the latter family, but which are reduced in the present to the mere space that encircles the eye.

Mr. Swainson thus defines the "*Tetraonidæ*, Partridges and Grouse:—Bill and tail very short; hallux elevated;" and he comprises under the family the following genera and sub-genera:—

Cryptonyx, Temm.; *Odontophorus*, Vieill.; *Ortygis*, Ill.; *Tetrao*, with the sub-genera *Tetrao*, Linn., *Lagopus*, Willughby, *Lyrurus*, Sw., *Pterocles*, Temm., and *Centrocercus*, Sw.; *Perdix*, Briss., with the sub-genera *Perdix*, *Chotopus*, Sw., *Coturnix*, Briss., *Ptilopachus*, Sw., and *Ortyx*, Steph.; *Crypturus*, Ill., with the sub-genera *Crypturus* and *Nothurus*, Wagl.

Prince Bonaparte makes the *Gallinæ* the third order of his second sub-class *Grallatores*; and this order comprises the families *Pteroclidæ*, *Phasianidæ*, *Tetraonidæ*, and *Crypturidæ*. The order next in succession to the *Gallinæ* is formed by the *Grallæ*.

Mr. G. R. Gray, in his 'List of the Genera of Birds,' arranges the *Tetraonidæ* between the *Phasianidæ* and the *Chionididæ*, with the following sub-families and genera:—

1. *Perdicinæ*.

Genera:—*Rhizothera*, G. R. Gray; *Ptilopachus*, Sw.; *Ithaginis*, Wagl.; *Lerwa*, Hodgs.; *Pternistes*, Wagl.; *Francolinus*, Briss.; *Chalcura*, Hodgs.; *Perdix*, Antq.; *Arborophila*, Hodgs.; *Coturnix*, Antq.; *Rollulus*, Bonn.; *Odontophorus*, Vieill.; *Ortyx*, Steph.; *Lophortyx*, Bonap.; *Callipepla*, Wagl.

2. *Tetraoninæ*.

Genera:—*Tetrao*, Linn.; *Lyrurus*, Sw.; *Bonasa*, Briss. (*Bonasia*, Bonap.); *Centrocercus*, Sw.; *Lagopus*, Briss.

3. *Pteroclinæ*.

Genera:—*Pterocles*, Temm.; *Syrphaptiles*, Ill.

The following species are European:—*Tetrao Urogallus*, the Capercaill-

zie, or Cock of the Wood; *T. hybridus*, Sparrm. (*T. medius*, Meyer), the Hybrid Grouse, generally considered by ornithologists to be a hybrid between the Capercaillie and the Black Cock; *T. tetrix* (genus *Lyrurus*, Sw.), the Black Grouse, or Black Cock; *Bonasia Europæa*, the Hazel-Grouse, or Gelinotte; *Lagopus Scoticus*, the Red Grouse; *L. mutus*, the Common Ptarmigan; *L. terrestris*, the Rock Ptarmigan; *L. Saliceti*, the Willow-Ptarmigan; *L. brachydactylus*, the Short-Toed Ptarmigan; *Pterocles arenarius*, the Sand-Grouse; *P. setarius*, the Pin-Tailed Sand-Grouse.

Of these the Black Cock, the Red Grouse, and the Common Ptarmigan, are British; to which we may now add the Capercaillie, restored by the care of the Marquis of Breadalbane and others. [CAPERCAILLIE.]

Lagopus mutus, the Common Ptarmigan, may be taken as an example.

Common Ptarmigan (*Lagopus mutus*) in winter and summer plumage. (Gould.)

This bird is supposed by some, and with good reason, to be the *Lagopus* of Pliny ('Nat. Hist.' lib. x., c. 48), who notices its excellent flavour, and states that its feet, with their 'hare-like hair,' gave the bird its name. It is the *Tetrao lagopus* of Linnaeus; *Lagopus vulgaris* of Fleming; *Pernice de Montagna*, *Pernice Alpestre*, and *Lagopo Bianco*, of the Italians; *Perdrix Blanche* and *Gelinote Blanche* of the French; *Perdiz Blanca* of the Spanish; *Schneehuhn* and *Haasenfussige* *Waldhuhn* of the Germans; *Rype* of the Norwegians; *Riupkarre* (male), *Riupa* (female), of the Icelanders; *Tarmachan* of the Northern Gael; and *Coriâr yr Alban* of the Welsh.

The winter plumage of the male is pure white; a black band proceeding from the angle of the bill and traversing the eyes; lateral tail-feathers black, terminated by a white border; feet and toes well covered with woolly feathers; above the eyes a naked space, which is terminated by a small dentilated membrane; these naked parts are red; claws hooked, subulate, and black; bill black; iris ash-coloured. Length about 15½ luehes.

The winter plumage of the female differs from that of the male in having the naked space above the eye less, and no black eye-band. Smaller than the male; the length about 14½ inches.

It is found in the north of Europe: Lapland, Norway, Sweden, Russia. The alpine districts of the middle and south of Europe. North America: the islands lying in the south-west of Baffin's Bay (Sabine); high hills keeping near the snow-line; Churchill River (Franklin; Richardson.)

In the British Islands it was formerly found in the north of England, and, as its Welsh name indicates, in Wales; but it no longer occurs in those localities, nor is it to be met with in Ireland.

On all the elevated summits of the north of Scotland it is not uncommon; and on most of the Grampians, but especially the great granite and slaty masses from which issue the sources of the Dee, the Spey, and the Tay, it may be said to be even abundant. Great numbers are annually killed, but as the haunts of this Ptarmigan are not so easily accessible as those of the brown species (*Lagopus Scoticus*), it is not at all likely to be exterminated.

The summer food of the Ptarmigan consists principally of alpine berries, and in winter of the shoots of young heath.

This species has been reared in confinement without any great difficulty, and has bred in a tame state. (Selby.)

Large numbers of Ptarmigan are sent from Norway to London every winter. In Norway the peasants take them in snares. The captured birds are kept in a frozen state till the dealers come, and one of these dealers will sometimes buy and sell 50,000 ptarmigans in a season. According to the calculation of Sir Arthur de Capell Brooke, 60,000 of these birds were killed during one winter in a single parish, which was however large. Mr. Grant informed Mr. Yarrell that he was assured, when in Norway, that the number of ptarmigan killed in that country every winter was beyond belief: 2000 dozen, if Mr. Grant remembered right, was the quantity exported from Drammen in one ship for England in 1839; and great numbers, he adds, are sent to the Copenhagen market. Mr. Yarrell goes on to state that, besides those brought to this country from Drammen, great quantities are also received in London, during the months of February, March,

April, and May, from Bergen, Drontheim, and other ports on the west coast of Norway, whence conveyance is obtained for them in the boats which bring constant supplies of lobsters to the Loudon market. "On one occasion," says Mr. Yarrell, "late in the spring of 1839, one party shipped 6000 ptarmigan for London, 2000 for Hull, and 2000 for Liverpool; and at the end of February, or very early in March of the present year (1840), one salesman in Leadenhall market received 15,000 ptarmigan that had been consigned to him; and, during the same week, another salesman received 700 capercaillies and 560 black grouse."

Pterocles arenarius, Temm., Barbary and Senegal; *P. guttatus*, Licht., Egypt; *P. quadricinctus*, Temm., Senegal; *P. coronatus*, Licht., Nubia; *P. Lichtensteinii*, Temm., Nubia; *P. tricoloratus*, Swain., Senegal; *P. exustus*, Temm., Egypt and Senegal; *P. tachypetes*, Temm., South Africa; *P. bicinctus*, Temm., South Africa; *P. simplex*, Roux., South Africa; *P. maculosus*, Burchell—are, according to Dr. Andrew Smith, all African species.

As an example of the African forms, we give a representation of *P. gutturalis*.

Pterocles gutturalis, male and female. (Smith.)

Dr. Smith states that this species was first discovered in 25° 40' N. lat., about 80 miles to the eastward of Latakoo; and it was when he remarked its cry to differ from that uttered by *Pterocles tachypetes*, Temm., that he was led to suspect that it was distinct. He says that, in common with the other South African species of this genus, it repairs in large flocks at regular and fixed periods to localities where water is, and that at such times specimens are most readily procured; but he warns the sportsman to be quick in his movements, as they scarcely reach the water before they are again on the wing. As they approach and recede from such spots, they almost incessantly utter cries resembling 'twet weet, twet weet.'

P. setarius, the Pin-Tailed Sand-Grouse, Gauga Cata, is an example of the Grouse of Asia.

This bird is very numerous on the arid plains of Persia. Not very numerous in France, on the sterile Landes near the Pyrenees, and along the coasts of the Mediterranean; less common in Provence and Dauphiné, where they occasionally arrive; more common in Spain, Sicily, Naples, and throughout the Levant. Temminck, who gives these localities, states, in the fourth part of his 'Mammels,' second edition, that it is common in Provence, in the uncultivated plains of Crau, and says that it avoids cultured tracts, and only inhabits the sterile Landes of the south; but he adds that it is abundant in the

Pyrenees, and that it is to be found all the year round in the markets of Madrid. Mr. Gould states that the species is found in the north of Africa. It feeds on seeds, insects, and the young shoots of plants.

Pin-Tailed Sand-Grouse (*Pterocles setarius*), male and female. (Gould.)

America possesses several species of Grouse, consisting of the genera and sub-genera *Bonasia*, or *Bonasa*, *Tetrao*, *Lagopus*, and *Centrocercus*.

Centrocercus urophasianus, is the *Tetrao urophasianus* of Prince C. L. Bonaparte, the Cock of the Plains of Lewis and Clark, and the Pygmie of the Kyuso Indians.

This grouse appears to have been first recorded by Lewis and Clark; and it has since become familiar to the fur-traders on the banks of the Columbia. Sir John Richardson gives an interesting account of its habits in the 'Fauna Boreali Americana.'

Nuttall says that the flesh is dark and less palatable than that of other species.

Cock of the Plains (*Centrocercus urophasianus*), male. (Swainson.)

Cryptonyx is a genus which has been variously placed, and by some amongst *Tetraonidae*. It has the following characters:—Bill strong, stout, compressed, convex above, curved towards the point; nostrils

Cryptonyx cristatus. Male in the front; female behind.

longitudinal, placed in the middle of the bill, and covered by a naked membrane; orbits and lore naked; hind toe without any nail, not touching the ground. Wings short; third, fourth, and fifth quills longest.

C. cristatus (*C. coronatus*, Temm.), is the Rouloul de Malacca of Sonnerat. According to Mr. T. C. Eyton, the Malay native name is Bestum. ('Catalogue of a Collection of Birds from Malaya,' &c., in 'Zool. Proc.', 1839.)

These beautiful birds haunt the great forests of Malaya, Sumatra, and Java. Wild and shy, they avoid the face of man, and are kept in captivity with great difficulty. [BLACK-CKOCK; CAPERCAL; BONASIA.]

TETRAONYX. [CHELONIA.]

TETRAPTERUS, a genus of Fossil Fishes. [FISH.]

TETRAO. [STRUTHIONIDÆ.]

TETRODON, a genus of Fishes of the order *Plectognathi*. These fishes, instead of having distinct teeth as usual in the class, have the jaws provided with a substance resembling ivory, formed somewhat like the beak of a bird, and fitted for crushing crustaceous animals and *Fuci*, upon which they live. Both the *Tetrodus* and *Diodons* (*Diodon*, Linn.), a very closely allied genus, have the power of inflating the body with wind, or rather a membrane which extends along the under side of the abdomen, which causes them to float on the surface of the water, without the power, it is said, of directing their course; the membrane, when inflated, gives to the fish an almost spherical form, and is usually defended by spines and prickles. The pectoral fins are rather small; and besides these and the tail fin, they have one dorsal and a ventral fin. The *Diodons* have but one large tooth above and below, and are usually protected by large strong spines. The *Tetrodons* are distinguished by the possession of four large large teeth, the jaws being each divided by a central suture. These fishes are confined to the seas of warm climates: some of them are called *Globe-Fishes*.

TEUCRIUM (from *Teucer*), a genus of plants belonging to the natural order *Lamiaceæ*, or *Labiata*. It has a tubular 5-toothed, nearly equal, or 2-lipped calyx. The tube of the corolla is shorter than the calyx, the upper lip is abbreviated and bipartite; the lower lip is longer, spreading, and trifid. The stamens are much exserted, and the cells of the anthers are confluent and spreading. The species are herbs and shrubs inhabiting most parts of the earth, and having a variable habit and inflorescence. Upwards 70 species are described. Of these comparatively few are known in this country. Some of them are cultivated in our gardens, and three are natives of the British Isles.

T. Scorodonia, Wood Germander, or Sage, has cordate downy petiolate-crenate leaves; the flowers are of a pale-yellow colour, with violaceous stamens, and are arranged in lateral and terminal 1-sided racemes; the stem is erect, hispid, pubescent, or nearly glabrous. It is a native of Europe in woody hilly situations, where the soil is dry and stony. It is not an uncommon plant in Great Britain. The smell and taste of this plant resemble very much the hop. In Jersey, where it is called *Ambroise*, the inhabitants use it as a substitute for hops in their beer; and by some persons the bitter given by the Germander is preferred to that of the hop.

T. Scordium, Water-Germander, has oblong-sessile downy serrated leaves; flowers purplish, arranged in axillary whorls, 2-6 flowers in each; the stem is procumbent and villous. It is a native of Europe and the temperate parts of Asia in boggy wet places. It is a rare plant in Britain. Its fresh leaves are very bitter and rather pungent, having a smell similar to garlic. It had once a great reputation in medicine, but is now seldom used; it might however be employed in cases where an aromatic bitter is desirable.

T. Chamedrys, Wall, or Common Germander, has ovate incised-serrate leaves, tapering into a footstalk; the flowers are reddish-purple, and arranged in axillary whorls of three flowers; the stem is ascending, and most frequently villous. It is a native of Europe and some parts of Asia, on walls and rocks and dry places. It is only rarely found in Great Britain.

T. Marum, Cat-Thyme, has small ovate quite entire leaves, with 2-4-flowered whorls; stem erect, branched. It is a native of the region of the Mediterranean. Cats are very fond of it, and destroy it when they get near it.

T. polium, Mountain Poly, has cuneate-oblong or linear leaves with revolute edges; whorls few, condensed into globular terminal heads; stems procumbent, much branched. This plant is a native of Europe and Africa, on the shores of the Mediterranean.

TEUTHIDÆ. [SEPIADÆ.]

TEXTOR. [FLOCEINÆ.]

THALAMITA. [PORTUNIDÆ.]

THALAMUS (from *θάλαμος*, the bridal chamber), a botanical term which was applied by Linnaeus to the calyx or outer whorl of floral envelopes. Tournefort applied the term to a receptacle that is not fleshy, but surrounded by an involucre. In this sense it is used in common with the terms *Clinanthium* and *Pboranthium*. By some writers, as De Candolle, the term is applied to the receptacle of all plants or that point of the rachis or stem around which the floral envelopes are seated. Thus those plants in which the petals and stamens are inserted into the receptacle constitute the first sub-class,

Thalamifera, of the Exogens, in De Candolle's natural arrangement of plants.

THALARCTOS. [BEAR.]

THALASSEMA. [SIPHUNCULOIDEA.]

THALASSEUS. [STERNIDÆ.]

THALASSIANS. [CHELONIA.]

THALASSIANTHUS, a genus of *Actinidae*.

THALASSIDROMA. [PROCELLARIDÆ.]

THALASSINA. [THALASSINIDÆ.]

THALASSINIDÆ, a family of Macrurous Decapodous Crustacea. The species of this small but interesting family resemble each other in appearance, and are remarkable for the extreme elongation of their abdomen, and the small degree of consistence of their integuments.

M. Milne-Edwards divides this family into two divisions:—

1. Cryptobranchida.

Under this group M. Milne-Edwards arranges all the *Thalassinidæ* which are without respiratory appendages suspended under the abdomen. Their branchiæ are in general composed of cylinders, united after the manner of a brush. All the species whose habits are known live in the sand, in which they burrow deeply.

Glaucothoe, Edwards.—Carapace nearly ovoid, and without any rostriform prolongation; eyes projecting, large, and nearly pyriform; internal antennæ short, cylindrical, and bent; external antennæ inserted lower than the preceding, their peduncle bent, and presenting above a small scale, the vestige of a palp.

G. Peronii is the only species known. It appears to inhabit the seas of Asia.

Callianassa, Leach. [CALLIANASSA.]

Asia, Leach.—Carapace very much compressed, and terminated anteriorly by a small triangular rostrum; ocular peduncles very small, cylindrical, and terminated by a hemispherical cornea. Terminal filaments of the internal antennæ nearly of the length of the carapace.

A. Stirrhynchus is the only known species. Its length is about three inches, and it inhabits the coasts of France and England.

Asia Stirrhynchus.

a, intermediate antenna; b, external antenna.

Gebia (*Gebios* and *Thalassina*, Risso; *Gebia* and *Upogebia*, Leach).—Carapace terminating anteriorly by a triangular rostrum, and sufficiently large to cover the eyes almost entirely; on each side of its base is a tooth, which is continued with a crest, and forms the lateral border of the upper surface of the stomachal region. Internal antennæ very short, but nevertheless their terminal filaments are longer than their peduncle; external antennæ very slender, and presenting at their base no vestige of a moveable scale.

G. stellata. Length an inch and a half. It inhabits the coasts of England.

Gebia stellata.

c, intermediate antenna; b, base of an external antenna.

Thalassina, Latreille.—Carapace short, narrow, and very much elevated. Stomachal region small, and limited backwards by a deep furrow. Cardial and intestinal regions equally separated from the branchial regions, and representing by their junction a triangle, the apex of which is directed backwards. Front armed with a small triangular rostrum. Eyes small and cylindrical. Internal antennæ inserted above those organs; their peduncle of moderate size, and their terminal filaments slender and unequal, the longest about thrice the length of the peduncle. External antennæ very small; their peduncle cylindrical, hardly reaching beyond the rostrum, and presenting above no vestige of appendages.

T. scorpionides. Length about 6 inches. Colour brownish. It is a native of the coasts of Chili.

Thalassina scorpionides.

2. Gastrobranchids.

M. Milne-Edwards observes that this small division of the Thalassians is very remarkable, for it establishes the passage between the *Callianassæ* and the *Squilla*. In the general form of the body the Crustaceans forming this division differ, he remarks, but very little from the first, and the conformation of their thoracic branchiæ does not permit their separation from the Macrurous Decapods, nor their distant removal from the Thalassiniæ; but they have respiratory appendages fixed to their abdominal false feet, exhibiting the greatest analogy with the ramosæ branchiæ of the Stomapoda.

Callianidea (Edwards).—Body very delicate, slender, and elongated; carapace hardly a third of the length of the abdomen, and not covering the last thoracic ring, compressed and rather elevated, its lower border applied exactly against the base of the four first pairs of feet. No

rostrum, and the anterior border of the carapace notched on each side of the median line for the reception of the base of the eyes, whose peduncles are very short, and formed as in the *Callianassa*. Four antennæ, slender, and inserted nearly on the same transversal line; the first pair terminated by two filaments nearly equal in length, one of which however is the largest, and slightly convex towards the end.

C. typa. Length about 10 lines. It is a native of the coasts of New Ireland, where it was found by Messrs. Quoy and Gaimard.

Callinidea typa, magnified.

a, antenna of the first pair; b, external jaw-foot; c, extremity of one of the posterior feet; d, abdominal false feet, first pair; e, false feet of one of the four succeeding pairs; f, marginal fringe of these false feet.

THALASSIOPHYTES (literally 'sea-plants,' from *θάλασσα* and *φύτον*) is the name given by Lamouroux to designate the vegetable productions of the ocean and of its rocks and shores.

THALASSIORNIS. [DUCKS.]

THALICTRUM (from the Greek *θάλικτρον*), a genus of Plants belonging to the natural order *Ranunculaceæ*. Its consists of herbs which have usually a fetid smell like rue, and hence are called Meadow Rue. The species have perennial roots with annual stems. The flowers are corymbose, panicle, and somewhat racemose, of a green, white, or yellow colour; they have no involucre and no petals; the calyx is composed of 4 or 5 petal-like sepals; carpels 4-15 in number. Upwards of 50 species are enumerated, which are mostly natives of the temperate and colder parts of the world.

T. aquilegifolium, Feather-Columbine, has ovate stipules, placed at the base of the ramifications of the petiole; and a corymbose panicle. It is a native of Europe, in woody districts of Germany, France, and Italy. The stems and stamens of this plant vary in colour, sometimes being greenish-white and sometimes purple. A variety is found in Austria with dark purple stems and stamens, and is called *T. a. atropurpureum*. Another variety, *T. a. formosum*, has the stamens dilated at the apex; whilst another has the stems green and stamens quite white, and is named *T. a. album*.

T. minus, Lesser Meadow-Rue, has the stem round, mealy, the flowers panicle, drooping, leaflets smooth, roundish, toothed at apex, glaucous, pericarps acute, furrowed. It is a native throughout Europe. In Britain it is found in chalky pastures, and on the sea-coast where shell-sand abounds. The *T. majus*, Greater Meadow-Rue, is also a native of Great Britain, though rare.

T. flavum, Yellow Meadow-Rue, has an erect branched furrowed stem, fibrous roots, a somewhat corymbose panicle of cream-coloured flowers, with wedge-shaped trifid acute leaflets. It is a native of all districts in Europe. In Britain it occupies wet meadows, the banks of rivers and ditches. It has a root of a yellow colour, and is said to resemble, both in appearance and properties, rhubarb. It yields a yellow dye, which may be employed for dyeing wool, and was formerly used as a remedy in jaundice. Like many of the family to which it belongs, it is very acrid, and produces blisters upon the skin, when applied to it.

T. fetidum, Fetid Meadow-Rue, has a simple stem, naked at the base, leafy in the middle, and panicle at top; the leaflets are obtuse, toothed, and covered with a clammy pubescence. It is a native of France, Switzerland, Russia, &c., and is found in valleys and on hill sides, and in the fissures of calcareous rocks. It smells more powerfully than any of the species—hence its specific name.

T. Cornuti has dioecious or polygamous flowers, with club-shaped filaments, obovate roundish leaflets, glaucous beneath. This is a North American species, and is found on the banks of rivers and in woody districts throughout the whole continent.

THALLOGENS, a class of Plants proposed by Lindley for those Flowerless Plants which are distinguished by the absence of an axial

stem. It includes all the *Cryptogamia*, with the exception of Ferns and Mosses. [ACROGENS.]

THALLUS is a botanical term used exclusively in cryptogamic botany, and is generally applied to the part of the plant which bears the reproductive organs, and constitutes the principal part of its vegetation.

THAMNOPHILI'NÆ. [LAMIADÆ.]

THAMNO'PHILUS. [LAMIADÆ.]

THAP'SIA, a genus of Plants belonging to the natural order *Umbelliferae*. The species are perennial herbs, with doubly or trebly pinnate leaves, large compound umbels of many rays without involucre or involucella, and yellow flowers. The margin of the calyx is 5-toothed; petals elliptic, entire; fruit compressed from the back; mericarps with five primary filiform ribs, three of which are dorsal, and two lateral ones in the commissure, and with four secondary ribs, of which the two dorsal are filiform and the two lateral ones membranous and winged; vittæ in each furrow underneath the secondary ribs.

T. villosa, Velvety Deadly Carrot, has a square glabrous stem; tri-pinnate leaves, many-parted leaflets, villous on both surfaces, lower ones deflexed. This plant is found in Portugal, Spain, the south of France, in Italy, and the northern coasts of Africa.

T. silphium, Silphium Deadly Carrot, has a square glabrous furrowed stem; pinnate leaves, many-parted leaflets, all linear, hairy on both surfaces, with revolute margins. It is a native of the north of Africa, on the mountains of Cyrenaica, and is supposed to be the plant that produced the juice called Silphium, and which was held in such high repute by the ancients, that a district where it grew in abundance was called 'Silphifera.' [SILPHIUM.]

T. Garganica, Garganian or Greek Deadly Carrot, has a square glabrous stem; bi- or tri-pinnate shining leaves; segments linear, acute, elongated, quite entire along the margins; involucre with few leaves; fruit cordate at the base. This plant is a native of Calabria, Mauritania, Greece, Sicily, Sardinia, Spain, &c. Dr. Sibthorp found it common in Greece and the neighbouring islands, and concludes that it is the *ἑλκυσία* of Dioscorides, with whose description it agrees better than any of the rest.

THAUMA'NTIAS. [ACALEPHÆ.]

THAUMA'SIA. [ALGÆ.]

THEA, a genus of Plants belonging to the tribe *Camelliæ* and natural order *Ternströmiaceæ*, which has been so named from the slightly altered Chinese name of the dried herb which now forms the almost universal beverage of the British Isles. Though now so extensively employed, the introduction of tea into Europe is of comparatively recent origin.

Tea however must have been used in China from very early times. It is differently named in different parts of China, as Tcha, or Cha, also Tha, whence we have Tsia, The, and Tea. In Persian works in use in India, tea is called Cha-Khuti, or Tea of Cathay.

The genus *Thea* is characterised by having a calyx which is persistent, without bracts, 5-leaved, leaflets imbricated, the outer ones smaller; petals of the corolla 6 to 9, hypogynous, imbricated, the inner ones the largest, all adhering together at the base; stamens numerous, in several rows, adhering to the bottom of the petals; filaments filiform, anthers incumbent, 2-celled, oblong, with a thickish connectivum, cells opening longitudinally; ovary free, 3-celled; ovules 4 in each cell, inserted alternately into the central angle, the upper ones ascending, the lower pendulous; style trifid, stigmas 3, acute; capsule spheroidal, 2-3-lobed, 3- or by abortion 2-celled, with loculicidal dehiscence, or with the dissepiments formed from the turned-in edges of the valves; seeds solitary or rarely two, in cells, shell-like testa, marked with the ventral umbilicus; cotyledons thick, fleshy, oily; no albumen; radicle very short, very near the umbilicus, centripetal.

The genus *Camellia* is usually considered to be very distinct from *Thea*; indeed by Cambessedes the two are separated from each other by several intervening genera: they are however too closely allied to allow of this separation. Distinctions have been made in the fruit of the two genera. That of *Thea* is 3-lobed with obtuse corners and opening along the middle of the lobes, that is, having the dissepiments opposite to the valves, or, as expressed by modern botanists, having a loculicidal dehiscence. *Camellia*, on the contrary, is described as having its fruit obscurely triangular, without any tendency to become deeply 3-lobed, with the margins of the valves turned inwards and forming the dissepiments, which thus alternate with the valves, and have what is now called a septicidal dehiscence. Mr. Griffith, on the contrary, who is well qualified to form a correct opinion, states, from examination of the Assamese tea-plant and of two species of *Camellia* from the Khosiya Hills, that there is no difference between *Thea* and *Camellia*. The dehiscence in both, he says, is of the same nature, that is, loculicidal, and the only difference that does really exist is simply of specific value, consisting in the fruits of the tea-plant being 3-lobed, of the *Camellia* triangular.

The species of the genus *Thea* are few in number; some botanists are of opinion that even these are varieties of a single species.

T. viridis is a large, strong-growing, almost hardy plant, with spreading branches, its leaves three to five inches long, thin, almost membranous, very broadly lanceolate, light green and wavy, with large and irregular serratures, the flowers large, usually solitary, mostly confined to the upper axil, with 5 sepals and from 5 to 7 petals; fruit

nodding. This species is figured by Dr. Lettson in his account of the tea-plant, t. 1, and by Sir W. J. Hooker, 'Bot. Mag.' t. 3148, and in Loddiges' 'Bot. Cab.' t. 227, all from plants which have flowered in this country. Krampfer supplies a very good figure, 'Amoen. Exot.' p. 607, from a Japanese plant. This species is found both in China and Japan, and is supposed to be the species which yields the green tea of commerce. It has been long introduced into this country; having been first sent from Japan in 1687 to the Cape of Good Hope, and thence into Europe.

T. Bohea is a smaller plant than *T. viridis*: its branches are stiff and straight, its stem erect, the leaves not above half or two-thirds of the size of the former species, elliptical oblong, perfectly flat, more coriaceous, of a dark green colour, with small and even serratures; they are numerous, and have in their axils two or three flowers, of 5 sepals and 5 petals, these are smaller and have a slight fragrance, and flower later in the season than *T. viridis*. The plant is much more tender than the green tea-plant, and unable to stand the cold of an English climate. It is supposed by some to yield the leaves which are converted into black tea, and, notwithstanding contrary statements, leaves similar to those of this plant may be recognised on infusing and spreading out the leaves of some of the black teas of commerce. [TERNSTROMIACEÆ.] A variety of this is sometimes called *T. stricta*. It is figured by Lettson, ed. 2, p. 41, who considers it only a variety of the former. It is also figured by Loddiges, 'Bot. Cab.' t. 226, who, as well as Sir W. J. Hooker and Dr. Royle, considers it to be a distinct species.

T. Assamensis, the Assam Tea-Plant, which some years ago attracted so much attention, seems to partake of the characters of both the foregoing. The Calcutta Tea Committee say, in 1835, "We are now enabled to state with certainty, that not only is it a genuine tea, but that no doubt can be entertained of its being the identical tea of China, which is the exclusive source of all the varieties and shades of the tea of commerce." To this it may be replied, that there are considerable doubts whether the teas of commerce are all derived from one species of plant. Mr. Griffith says, in the size both of the plant and of the leaves, as well as in the texture of these last, and in its stations, the Assamese plant approaches to the green tea-plant of China; in its geographical distribution, so far as latitude is concerned, it approaches to the black tea. The inflorescence of the Assamese plant varies, but perhaps its usual state is to have the flowers solitary in the axils of the leaves, but the number of flowers varies from one to five. The plants introduced into this country have their leaves much larger and thicker than those of the green tea-plant, and Messrs. Loddiges find that it requires a much greater degree of heat, in fact that of the hot-house, while the others are in the open air for a great part of the year.

Two other species, described by Loureiro, are little known, as *T. Cochinchinensis*, about eight feet high, having lanceolate leaves, flowers of three to five sepals and five petals, solitary, terminal; found wild in the north of Cochinchina, where it is also cultivated, being used medicinally by the natives as a diaphoretic. *T. oleosa* is also a shrub of eight feet high, found in the fields in the neighbourhood of Canton, and named from its seeds yielding a large quantity of oil, which is used for burning and as an article of diet. The leaves are lanceolate, the flowers of six sepals and six petals, peduncles 3-flowered, axillary; fruit stated to be indehiscent, rather a berry than a capsule. [TEA, in ARTS AND SC. DIV.]

THECA (in Anatomy) is a term commonly applied to the strong fibrous sheaths in which certain soft parts of the body are inclosed. Thus the *Theca vertebralis* is the sheath of dura mater in which the spinal cord is inclosed; and the canals through which many of the long tendons of the muscles of the hand and foot run are called theca.

The same term is employed in vegetable anatomy. It was applied by Grew to that part of the stamen which contains the reproductive granules, and which is now generally called the anther. [ANTHER.] It is also extensively employed in cryptogamic botany. Among the ferns, it is applied, in common with the terms capsule, conceptacle, and sporangium [SPORANGIUM], to those little granules which constitute the masses called Sori. In the *Equisetacea* it expresses the assemblage of cases which are attached to scales arranged in a conical manner.

The same term is used to indicate the kidney-shaped two-valved cases that contain the reproductive matter of *Lycopodiaceæ*, and also the urn-like organs that inclose the sporules of mosses. It is by some writers still further extended, and used to express the parts that contain the sporules in Lichens and Fungi.

THECACTYLUS. [GECKOTIDÆ.]

THECIDÆA, or THECIDIUM. [BRACHIOPODA.]

THECODONTOSAURUS, a genus of extinct Saurian Reptiles referred by Professor Owen to his group of Thecodont Lacertians.

Professor Owen, in his 'Report on British Fossil Reptiles,' observes that among the inferior or squamate saurians there are two leading modifications in the mode of attachment of the teeth, the base of which may be either ankylosed to the summit of the alveolar ridge, or to the bottom of an alveolar groove, and supported by its lateral wall. These modifications are, he remarks, indicated respectively by the terms 'acrodont' and 'pleurodont.' A third mode of fixation is presented by some extinct saurians, which, in other parts of their

organisation, adhere to the squamate or lacertine division of the order, the teeth being implanted in sockets, either loosely or confluent with the bony walls of the cavity: these Professor Owen has, in his 'Odontography,' termed the Thecodont Lacertians, the most ancient of all saurians belonging to this group.

The *Thecodontosaurus* of Dr. Riley and Mr. Stutchbury, described by them in the 'Geological Transactions' of 1836, from remains found in the dolomitic conglomerate of Redland, near Bristol, the oldest or lowest division of the new red-sandstone series, is allied to the typical Varanian Monitor, but differs from them in having the teeth imbedded in distinct sockets. The *Varani*, among the squamate saurians, approach to this condition in the shallow cavities containing the base of their teeth along the bottom of the alveolar groove.

But, in the extinct genus now under consideration, the sockets are deeper, and the inner alveolar wall is nearly as high as the outer one; the teeth are arranged in a close-set series, slightly decreasing in size towards the posterior part of the jaw; each branch of the lower jaw is supposed to have contained 21 teeth, which are conical, rather slender, compressed and acutely pointed, with an anterior and posterior finely-serrated edge, the serratures being directed towards the apex of the tooth, as in G. Fischer's genus *Rhopalodon*; the outer surface is more convex than the inner one; the apex is slightly recurved; and the base of the crown contracts a little to form the subcylindrical fang. The pulp-cavity remains open in the base of the crown; and in their microscopic structure the teeth of the *Thecodontosaurus* closely correspond with those of *Varanus*, *Monitor*, and *Megalosaurus*.

The tooth of *Palæosaurus* is compressed, pointed, and with trenchant serrated margins; but its breadth, compared with its length, is much greater than in *Thecodontosaurus*. [PALÆOSAURUS; TELEOSAURUS.]

Professor Owen draws the following conclusions from the knowledge at present possessed of the osteology of *Thecodontosaurus* and *Palæosaurus*, whose antiquity the discoverers of these genera regard as being greater than that of any other vertebrated animals, excepting fishes:—

In their thecodont type of dentition, biconcave vertebrae, double jointed ribs, and proportionate size of the bones or the extremities, they are nearly allied to the *Teleosaurus*; but they combine a lacertian form of tooth and structure of the pectoral and probably pelvic arch with these crocodilian characters, having distinctive modifications, as the moniliform spinal canal, in which however the almost contemporary *Rhyuchosaurus* participates.

THECODONTUS. [THECODONTOSAURUS.]

THECOSO'MATA (Gray), an order of Pteropodous *Mollusca*, it includes the following families and genera:—

Family 1. *Cleodoridæ*.

Genera:—*Hyalæa*; *Diacria*; *Cleodora*; *Balantium*; *Pleuropus*; *Vaginella*; *Crescis*; *Brochus*; *Psyche*; *Euribia*.

Family 2. *Limacinidæ*.

Genus, *Limacina*.

Family 3. *Cuvieridæ*.

Genera:—*Cuvieria*; *Tripterus*.

Family 4. *Cymbulidæ*.

Genus, *Cymbulia*.

THELI'DOMUS, (Swainson), a genus of *Mollusca* placed in the family *Trochidæ*, and in the sub-family *Rotellinæ*. This so-called shell, which is twice figured and described as that of a mollusc in the 'Cabinet Cyclopædia,' is the case of an insect.

We notice the error, that a mistake in a useful book bearing the authority of a name so generally known and deservedly respected as Mr. Swainson's, may not mislead.

THELODUS, a genus of Fossil Fish. [FISH.]

THELPHUSÆ. [THELPHUSIDÆ.]

THELPHUSIDÆ, a tribe of Brachyurous *Crustacea* belonging to the family *Catometopes*. The carapace has but little or no convexity, and is wider than it is long: its anterior border is straight, and occupies about two-thirds of its transversal diameter: its lateral borders describe a regular curve. The front is remarkably wider than the buccal frame, and more or less curved downwards. The eyes have a stout and short peduncle, the length of which is never more than double the diameter, and its lower surface is occupied by the cornea for about half its length. The orbits are oval, and always present at their internal angle a narrow gap filled by the external antenna. The internal antennæ are horizontal, and, in general, nearly entirely hid by the front. The basilar joint of the external antennæ penetrates into the gap which occupies the internal angle of the orbit and separates this cavity from the antennary fossets; it is but little developed, and the moveable stem which springs from it in the same gap is very small.

The habits of these animals are very remarkable. All the known species live in the earth near the banks of rivers or in humid forests; bearing a strong analogy to the Land-Crabs. (Milne-Edwards.)

M. Milne-Edwards divides the tribe into three sections:—

1. Third joint of the external jaw-feet nearly square, and giving insertion to the succeeding joint by a notch in its internal angle.

Ex. *Thelphusa fluviatilis*. Length 2½ inches. Colour yellowish. It is found in the south of Italy, Greece, Egypt, and Syria.

This species is generally considered to have been well known to the ancients, and to be that noticed by Hippocrates and Aristotle: these *Theiphusæ* are supposed to be the Heracleotic Crabs (*οἱ Ἡρακλεωτικοὶ καρκίνοι*) of the latter ('Hist. Anim,' iv. 2); and to be those represented on ancient medals. It burrows in the earth on the banks of rivers.

Theiphusa fluvialilis, reduced. a, external jaw-foot of same.

2. Third joint of external jaw-feet nearly square, and giving insertion to the succeeding joint towards the middle of its anterior border.

Ex. *Boscia dentata*. Length about 2 inches. It inhabits the Antilles and South America.

Boscia dentata, reduced one-third. a, antennary region; b, external jaw-foot.

3. Third joint of the external jaw-feet having nearly the form of a reversed triangle, and giving insertion to the succeeding joint by its external angle.

Ex. *Trichodactylus quadratus*. Length about an inch. It is a native of Brazil.

THEMISTO (Guerin), a genus of Amphipodous Crustacea.

THENARDITE, Anhydrous Sulphate of Soda, a Mineral, occurring crystallised. Primary form a right rhombic prism. Cleavage parallel to the primary planes. Colour white or reddish. Transparent; translucent; opaque. Soluble in water; effloresces on the surface. Specific gravity 2.73.

It occurs in crystalline coatings at the bottom of some lakes, at a place called Las Salinas Espartinas, about five leagues from Madrid. It is used in the preparation of carbonate of soda. According to the analysis of Casaseca it is composed of—

Sulphate of Soda	99.78
Carbonate of Soda	0.22
	—100

THENUS. [SCYLLARIDÆ.]

THEOBROMA (from *θεός* and *βρώμα*, the food of gods), a genus of Plants belonging to the natural order Sterculiaceæ, the species of which yield the Cocoa of commerce. They are trees with large simple leaves and with the flowers in clusters. The calyx is composed of 5 sepals; the petals are 5, lengthened into a strap-like form at the apex; the stamens are 5, each with double anthers and a horn-like appendage between each filament; the style is filiform, with a 5-parted stigma; fruit a 5-celled capsule without valves; seeds imbedded in a soft pulp; no albumen, and thick oily wrinkled cotyledons.

T. Cacao, Common Cacao, or Chocolate Nut-Tree, has entire, elliptic, NAT. HIST. DIV. VOL. IV.

oblong, acuminate, quite smooth leaves, and oblong smooth fruit. This tree is indigenous in South America, and is generally found at a height of 600 feet above the level of the sea. It is however extensively cultivated in the West Indies, and in the tropical parts of Asia and Africa. The Mexicans call the tree Chocolate, hence our word Chocolate for the prepared seeds. The capsules of the fruit are large, and contain each about 25 seeds: the pulp in which these are enveloped has a sweet and not unpleasant taste, and is frequently eaten where the tree is grown. The trees are evergreens, and bear fruit and flowers all the year through, but the usual times for gathering the fruit are in June and December. The cotyledons of the seeds contain a large quantity of oily albumen, which has an agreeable flavour, and on this account they are not only used as a principal article of diet by the natives of the countries in which they grow, but are now used for the same purpose throughout the civilised world. The composition of these seeds, in which amylaceous matter is combined with oil, and a principle, called Theobromine, similar in its constitution to Thein and Caffein, is well adapted, when combined with sugar, to form a valuable article of diet. [Food.]

The oil contained in the seeds is sometimes obtained separately, and called cocoa-butter. It may be obtained easily by expression, especially if hot-water is added. It is said to be very nutritive, and to act as an anodyne. It is particularly recommended for making ointments. (Erech and Gruber, 'Allgem. Encycl.,' art. Cacao.)

There are several other species of *Theobroma*, yielding seeds possessing the properties of the above, but they are not cultivated or employed to the same extent. They are all of them natives of South America, and used by the inhabitants where they grow as food. *T. Guazuma* of Linneus, the Bastard Cedar, or Ormo d'Amérique, now the *G. ulmifolia*, is a native of the West Indies, and is a handsome tree resembling the elm.

THEONIA. [MILLEPORIDÆ.]

THEONOA, a genus of Fossil Zoophyta.

THEOPHRASTA, a genus of Plants dedicated to Theophrastus. It was originally called *Eresia* by Plumier, but afterwards altered by Linneus. *T. Jussieu* belongs to the natural order Myrsinaceæ, and is a small tree with a simple unbranched stem, furnished with a tuft of long evergreen leaves at top, giving it a resemblance to a palm-tree. The flowers are of a white colour, and are arranged on terminal racemes, which are very short, and hidden amongst the leaves of the plant. The calyx is campanulate and cartilaginous. The corolla is also campanulate, with a short tube, and has a dilated throat, girded by an elevated angularly-lobed, fleshy, arched ring: the limb is spreading. The stamens are five, combined with the tube of the corolla; anthers horned. The fruit is a crustaceous spherical berry, about the size of a crab-apple, with the seeds half immersed in the placenta. The *T. Jussieu* is the only species. It is a native of the mountains of St. Domingo, and is much cultivated on account of its long handsome holly-like leaves. It may be propagated by cuttings, and grows well in a soil of peat, loam, and sand.

THERATES. [CTENOSTOMA.]

THERISTICUS, a genus of Birds.

THESPE'SIA (from *θεσπέσιος*), a genus of Plants belonging to the natural order Malvaceæ. The species are trees with large entire leaves. The calyx is truncate, and girded by a 3-leaved deciduous involucre; the fruit is a capsule with 5 cells, and each cell is semi-parted, with 4 seeds at the base.

T. populnea, Popular Thespesia, has roundish cordate pointed 5-7-veined leaves, with dot-like scales beneath, with the peduncles equal in length to the petioles. This plant is a native of the East Indies, Guinea, and the Society Islands; and is known, where it grows amongst British colonists, as the Umbrella-Tree. It attains a height of about 40 feet, and has large yellow flowers with a dark-red centre. In the tropics it has gained for itself a sacred regard, and is planted about monasteries and convents; hence the name Thespesia (divine). There are two species, natives of South America: they are all trees, with handsome showy flowers.

THETIS, a genus of Fossil Shells.

THIA, a genus of Crustacea. *T. polita* is a British species. It lives buried in the sand at a small distance from the shore. The colour is rosy. Length 10 lines.

Thia polita.

THINOCORUS (Eschscholtz), a genus of Birds placed by Mr. G. R. Gray in his sub-family *Thinocorinae*.

THIROPTERA. [CHEIROPTERA.]

THIRST is the peculiar sensation which excites the desire to drink. Water is the proper object of this desire. [FOOD.]

THISTLE, the common name of *Carduus*, a genus of Plants belonging to the large natural order *Compositae*. From the time of Theophrastus down to that of Caspar Bauhin, all plants that possessed a spiny involucre were comprehended in the genus *Carduus*. The Artichoke (*Cynara*) and the Teasel (*Dipsacus*) were included in it by Tragus and Lobelina. Morison confined the genus to those plants that had spiny scales of the involucre and a crown of feathery down (pappus) surmounting the seed. Plants resembling them, but without a spiny involucre, he called *Cirsium*, and those without the feathery pappus *Carduus improprie dictus*. Tournefort adopted these distinctions. Vaillant defined *Carduus* more accurately, giving it to plants with a globular involucre composed of spiny scales, with compound flowers, tubular florets, stamens united by the anthers, a hairy receptacle, and a hairy pappus on the seeds. If the pappus was feathery, he called the genus *Acama*; and when the receptacle was not hairy, but honeycombed, he used the term *Onopordon*, a name previously applied to Thistles by Pliny. When the scales and receptacles were fleshy, he named the genus *Cynara*. Linnaeus adopted these genera, but changed Vaillant's *Acama* into *Oniscus*, a name which had been previously employed by Tournefort for another genus.

The genus *Carduus* consists of upwards of 30 species, most of which are inhabitants of Europe. None of them are found in the New World.

C. nutans, Musk-Thistle, has decurrent spiny leaves, with handsome drooping flowers; the scales of the involucre cottony, the outer ones spreading. It is a common plant on waste ground, in dry, stony, or chalky soils, in Great Britain. It gives out, especially in the evening in warm weather, a strong smell of musk.

C. marianus, Milk-Thistle, has spinous leaves embracing the stem; the scales of the involucre leaf-like, recurved and spinous at the margin. It is a native of England; scarce in Scotland. The leaves are distinguished by the milky-whiteness of their veins. This milkiness is said, according to an absurd story, to have been produced by a drop of the Virgin Mary's milk, just as the Milky-Way was supposed to arise from that of Juno. This plant is an esculent, and may be eaten young as a salad, or boiled and eaten as greens. The young stalks, when peeled and soaked in water, are also excellent.

The root may be prepared like salsify and skirret, and the receptacle may be cooked and eaten as the artichoke. When cultivated, the seeds should be sown in spring, and the plants kept at a foot and a half distance from each other, and the earth thrown up round them till they are etiolated.

The genus *Oniscus*, Plume-Thistle, is known by the feathered down that crowns the seeds. It is a large genus; nine of the species are inhabitants of Great Britain.

The Cotton-Thistle is the *Onopordon*, which is known by its honeycombed receptacle. The *O. Acanthium* is a British species. The leaves are ovate-oblong, sinuated, spinous, decurrent, and woolly on both sides. It attains a height of from four to six feet. It is cultivated in Scotland as the Scotch Thistle; but it is doubtful whether this national badge has any existing type, as the representations of the Scotch Thistle on ancient wood-carvings, coins, and armorial bearings, differ more from each other than any known species of thistles. The receptacle and stalks of the Cotton-Thistle are sometimes eaten in the same manner as the Artichoke and Cardoon. [CYNARA.]

The Carline Thistle forms the genus *Carlina*, which obtained that name from a tradition that the root of the Common Carline (*C. vulgaris*) was shown by an angel to Charlemagne as a remedy for the plague which prevailed in his army. The genus is known from the others by the inner scales of the involucre being spreading and membranous, and of a yellow colour. The Common Carline is a frequent plant in Great Britain on dry hilly pasture and in fields. It is about one foot high.

The Blessed Thistle is the *Centaurea benedicta*, the *Carduus benedictus* of old writers. The involucre of the genus *Centaurea* is not spiny, and the seeds have a very simple pappus, or none. The Blessed Thistle is a native of the Levant, and in the middle ages was held in extravagant estimation on account of its supposed virtues. It is still cultivated in some places on account of its medicinal properties.

Sow-Thistle is the name given to the species of *Sonchus*. [SONCHUS.]

TILLASI (from *tlāca*, to compress; seeds compressed), a genus of Plants belonging to the natural order *Cruciferae*, and the sub-order *Angustisepala*. It has a roundish notched pouch, boat-shaped valves winged at the back; the seeds are numerous, the petals equal, the flowers white.

T. arvensis, Penny-Cress, has oblong-toothed leaves and erect stems, an elongated fruit-bearing raceme, orbicular pouches with a longitudinal wing. It is a native throughout Europe and in England. The flowers are small and white, and the whole plant when bruised has a somewhat alliaceous odour.

T. perfoliatum has obcordate pouches, the stem-leaves cordate-oblong, the petals equal in length to the calyx. It is a native of Europe and is found in England on a chalky soil.

T. alpestris is found on limestone mountain pastures throughout Europe and England; the leaves are entire, the radical ones ovate, stalked, the cauline ones sagittate and stem-clasping; the petals nearly as long as the calyx, the pods obcordate, 8-12-seeded.

THOA (Linnaeus), a genus of *Polyporiaria*.

THOMSONITE. [COMITONITE.]

THORACIC DUCT is the principal trunk of the lymphatic or absorbent system, and the canal through which the greater part of the chyle and lymph is conveyed into the blood. It commences, below, at what is called the receptaculum chyli, which receives all the principal absorbent vessels from the intestines and from the lower extremities, and lies at the posterior and middle part of the abdomen, on the upper lumbar vertebra and on the right side of the aorta. In man the diameter of the receptaculum is but little greater than that of the thoracic duct, which is continued from it; in most other animals it is considerably greater, and the duct seems in them to commence in a large pouch. From the receptaculum chyli the thoracic duct passes upwards, on the right side of the aorta, and behind it, from the abdomen into the chest, being joined in its course by the lymphatic vessels of the adjacent organs. Opposite the sixth dorsal vertebra it begins to bend to the left, and, after passing behind the arch of the aorta, it ascends to the level of the seventh cervical vertebra, curves forwards and downwards, and opens into the left subclavian vein, usually near its junction with the left jugular vein. At this orifice of the thoracic duct there are two valves, like those of the veins, which open to permit fluid to pass from the duct, but close when any is forced against them from the vein. Other valves in uncertain number are found in different parts of the duct, and have all the same direction as those of veins. [ABSORBENTS; CHYLE; DIGESTION.]

THORAX. [LUNGS.]

THORITE, a Mineral in which thorina was discovered to exist by Berzelius. It occurs massive and compact. Fracture uneven, very brittle, and full of cracks. Hardness about 5.0. Lustre resinous; vitreous; opaque. Colour black. Specific gravity 4.63 to 4.80. Before the blow-pipe, gives off water, and becomes yellow, but does not fuse. It is found in Sienite, in Norway. It contains nearly 53 per cent. of thorina, mixed with 13 metallic and other bodies.

THORIUM, or **THORYNUM**, a metallic body discovered by Berzelius in an earth to which he had given the name of Thorina. [THORITE.]

THORN. [CRATÆGUS.]

THORN-APPLE. [DATURA.]

THOROUGHWORT. [EUPATORIUM.]

THOROW-WAX. [BUPLEURUM.]

THRA'CIA (Leach), a genus of *Mollusca*.

THRASA'ETOS. [FALCONIDE.]

THRAULITE, *Hisingerite*, *Hydrated Silicate of Iron*, a Mineral occurring in roundish nodules. Fracture uneven or imperfect, conchoidal. Structure curved, foliated. Brittle. Splendent. Nearly opaque. Lustre vitreo-resinous. Colour brownish-black. Gives out water when heated in a glass tube; imperfectly fused by the blow-pipe, and is, after heating attracted by the magnet. It occurs at Riddarhyttan in Westmanland (1), and at Bodeumais in Bavaria (2), accompanying iron pyrites. Its analyses by Hisinger and Kobell are as follows:—

	(1) Hisinger.	(2) Kobell.
Silica	36.30	31.28
Peroxo of Iron	44.39	50.86
Water	20.70	19.12
	101.39	101.26

THRIFT, the common name of the *Statice Armeria*, Smith, now *Armeria maritima*. *Armeria* belongs to the natural order *Plumbaginaceae*. It is distinguished by the flowers being in a head contained in an inverted cylindrical sheath, and the capsular fruit not bursting.

A. maritima, Thrift, is a common British plant, growing on muddy and rocky sea-shores and on the banks of salt-water estuaries. It bears transportation to gardens, where it is a favourite in forming the borders of flower-beds. It may be easily distinguished from other species by its linear 1-nerved leaves. It has rose-coloured flowers. Several varieties are described.

(Babington, *Manual of British Botany*.)

THRIN'CIA, a genus of Plants belonging to the natural order *Compositae* and the sub-order *Cichoraceae*. It has an oblong involucre in one row, with a few additional scales at the base; the receptacle is punctured; the fruit beaked; the pappus in two rows, the outer row setaceous, deciduous, the inner one longer, feathery, and dilated at the base; the marginal row of fruits enveloped in the scales of the involucre.

T. hirta, the only British species, has lanceolate leaves, sinuate, dentate, hispid or hairy; the leaves are all radical, sometimes nearly or quite entire, occasionally runcinate. It is found chiefly in gravelly soil.

(Babington, *Manual of British Botany*.)

THIR'OTHORUS. [TROLODYTINE.]

THIROTHURUS. [TROLODYTINE.]

THROMBOLITE. [COPPER.]

THROSCUS. [ELATERIDÆ.]

THROSTLE. [MERULIDÆ.]

THRUSH. [MERULIDÆ.]

THRUSH-FUNGUS. [OIDIUM.]

THRUSHES. [MERULIDÆ.]

THUJA, or THUYA, a genus of Plants belonging to the natural order *Coniferae*. This name is derived from *θύω*, as, on account of the pleasant odour given out by the wood in burning, it was used in ancient sacrifices. The species of this genus are more commonly known by the name of *Arbor Vita*. It belongs to the section of *Coniferae* called *Cupressinae* by Richard, in which *Cupressus*, *Callitris*, *Taxodium*, and *Juniperus* are also included. The pistils and stamens are in separate flowers on the same tree. The male catkins are terminal and solitary; the pollen of each flower is included in four cases that are attached to the inner face of the scale towards its base. The female catkin is terminal; the ovary is united to the bractea, forming together a kind of receptacle; each receptacle has two ovules; the receptacles are semipeltate, imbricated, and smooth, or, in some cases, have a recurved beak near the tip; the seeds in some are slightly winged. The leaves are scale-like, closely imbricated or compressed. The species are evergreen, either trees or shrubs, and are inhabitants of Asia, Africa, and North America.

T. occidentalis, Western or American *Arbor Vita*, has the branchlets 2-edged; the leaves imbricated in 4 rows, ovato-rhomboid, adpressed, and tuberculated; the cones are obovate, with the interior scales truncate and gibbous beneath the apex. This plant is a large shrub or small tree, and is a native of North America, from Canada to the mountains of Virginia and the Carolinas. It is not so frequent in the southern states, and is found there on the steep banks of mountain-torrents. In the northern states of America it is sometimes called the White Cedar, but more commonly *Arbor Vita*. It grows best in cool moist places, on the borders of rivers and lakes, and in swamps, some of which it covers to the extent of 50 to 100 acres. The stem of this tree seldom rises straight from the ground, but makes a short bend before it becomes straight.

T. orientalis, Oriental or Chinese *Arbor Vita*, has 2-edged branchlets; imbricated ovato-rhomboid adpressed leaves, furrowed in the middle and in 4 rows; the cones are elliptic, with the interior scales blunt, and mucronate beneath the apex. It is a native of rocky situations in Siberia and China, and on the mountains of Japan.

T. pendula, Pendulous or Weeping *Arbor Vita*, has opposite decussating spreading lanceolate mucronate keeled somewhat distant leaves; globose cones; convex smooth scales; filiform pendulous branches. It is a native of Tartary, and is an elegant shrub.

T. articulata of Desfontaines is now called *Callitris quadrivalvis*, Four-Valved *Callitris*. The genus *Callitris* differs from *Thuja* in having the scales of the female catkins, from 4 to 6 in number, opening like the valves of a regular pericarp, and the seeds at the base of these scales winged on the margin. The Four-Valved *Callitris* has flattened articulated leaves; the female catkin with 4 oval pointed valves, 2 of which have seeds. It is a native of Barbary, and attains a height of from 15 to 20 feet. It was first discovered by Desfontaines on Mount Atlas in 1796. [CALLITRIS.]

THULITE. [EPIDOTE.]

THUMERSTONE, or THUMITE. [AXINITE.]

THUNBERGIA (in honour of Thunberg the botanist), a genus of Plants belonging to the natural order *Acanthaceae*. It has a double calyx, the outer one 2-leaved, the inner about 12-toothed. The corolla is campanulate; the capsule beaked and 2-celled. The species are handsome climbing plants with a fragrant odour.

T. fragrans has a climbing stem, with cordate acuminate leaves somewhat angular at the base.

T. grandiflora has large flowers with no inner calyx; the leaves are angular cordate; the anthers bearded and spurred. This and the former species are natives of the East Indies.

THUREA. [BOSWELLIA.]

THURINGITE. [IRON.]

THUYTES, a genus of Fossil Plants.

THYLACINUS. [MARSUPIATA.]

THYLACOTHERIUM. [MARSUPIATA.]

THYMALLUS. [SALMONIDÆ.]

THYME. [THYMUS.]

THYMELACEÆ, *Daphnads*, a natural order of Plants belonging to the tubiferous group of Incomplete Exogens. The name of this order is derived from *Thymelæa*, a plant spoken of by the ancients, and which some have supposed to be the *Daphne Gnidium*, a plant belonging to the present order. This order consists of shrubs or small trees, very rarely herbaceous, with non-articulate sometimes spiny branches having a very tenacious bark. The leaves are entire, simple, without stipules, and alternate or opposite. The flowers are capitate or spiked, terminal or axillary, occasionally solitary; the calyx is tubular, coloured, 4-cleft, with an imbricate aestivation; the stamens are 2, 4, or 8 in number, inserted into the tube with 2-celled anthers, dehiscing lengthwise in the middle; the ovary is solitary, with a solitary pendulous ovule. The fruit is hard and dry, or drupaceous. The seed has little or no albumen, a straight embryo, with a short radicle and entire cotyledons. This order is related to *Santalaceae*, from which it differs in its inferior calyx. It is also allied to *Elæagnaceae*

and *Proteaceae*, from both of which it is distinguished by its pendulous ovules. Lindley refers to this order Bartling's *Anthoboleae*, on account of their superior fruit. The species are found in Europe, but are not common; they occur in greatest abundance in the cooler parts of India and South America, at the Cape of Good Hope, and in Australia.

The most prominent property of this order is their causticity, which resides in their bark. When applied to the skin it produces vesication, and pain in the mouth when chewed. The bark of several of the species is very tough, and may be manufactured into cordage. *Passerina tinctoria* yields a yellow dye, which is used in the south of Europe to colour wool. The various species of *Daphne* possess active properties; some are used for dyeing, some are poisonous, and the *Daphne Lagetta* is the Lace-Bark-Tree of Jamaica. [DAPHNE.]

Daphne Mezereum.

1, cutting with flowers; 2, ditto with fruit; 3, single flower; 4, calyx opened, showing the insertion of the stamens; 5, section of ovary, showing the single pendulous seed.

THYMUS (*θύμος*), the name of a genus of Plants belonging to the natural order *Lamiaceae* or *Labiatae*. It has an ovate bilabiate calyx with 13 ribs; the upper lip is trifid, the lower lip is bifid with ciliated subulate segments, and throat villous inside; the corolla with the upper lip erect, nearly plane, notched, lower patent and trifid; stamens straight, exserted; anthers 2-celled; styles bifid at apex. All the species are small under-shrubs with usually purplish flowers. Between 20 and 30 species have been described by botanists, most of them inhabitants of Europe, especially the region of the Mediterranean; one only is a native of the British Isles.

T. vulgaris, Common or Garden Thyme, is an erect plant, or sometimes procumbent at the base, or clothed with a hoary pubescence; the leaves are sessile, linear, or ovato-lanceolate, acute, with revolute edges, fasciated in the axils; the teeth of the upper lip of the calyx are lanceolate, but the segments of the lower lip are subulate and ciliated. This plant is a native of the south-west parts of Europe, in dry plains and on hills, and uncultivated places free from woods. It is very much branched, and has purplish flowers. This species is cultivated for culinary purposes, and many varieties of it are met with in gardens. It has a pungent aromatic odour and taste.

T. Chamædrys, Wild Thyme, or Mother-of-Thyme, is a suffrutescent plant, with whorled or capitate flowers, branched decumbent stems, with plain ovate obtuse entire petiolate leaves, more or less ciliated at the base; upper lip of the corolla ovate, 4-angular; upper lip of the calyx with short ovato-lanceolate leaves, with subulate ciliated teeth. It is a native of Great Britain, on hills and in dry pastures, and throughout Europe and the north of Asia. This plant has the same sensible properties as the last. One of the varieties is known by the name of Lemon-Thyme, on account of its scent resembling the lemon.

T. Serpyllum, Linnaeus, appears to be different from the above, having uniformly hairy prostrate creeping stems, distinct from the ascending capitate flower-stems. It is not a native of Great Britain.

T. mastichina, Mastich-Thyme, or Herb-Mastich, has ovate or oblong obtuse petiolate leaves, narrowed at the base and not ciliated; the calyx is villous, with feathery subulate teeth, which are longer than the tube. It is a native of dry sandy uncultivated places in Spain, Portugal, and Barbary. It exhales a scent resembling mastich. It is

the *Marum vulgare* of older botanists, and at one time had some reputation as an errhine.

THYMUS GLAND (which in the calf and lamb is called the Sweetbread), is an organ situated behind the sternum, in the anterior mediastinum, in front of the pericardium and the large vessels arising from the base of the heart. In the embryo and the infant it has, in proportion to the rest of the body, a very considerable size; in after-life it becomes comparatively smaller, and at last nearly disappears. It is of an elongated form, its greatest dimension being from above downwards, and is composed of two chief portions, which by careful dissection may be separated in the middle line. At each end it bears two processes, or horns, of which the upper are longer and more slender than the lower, and the right are usually longer than the left. It is supplied by several branches from the internal mammary, inferior thyroid, and mediastinal arteries, to which veins of considerable size correspond. Its absorbent vessels are numerous and large, but not more so than in other glands of equal vascularity.

The Thymus Gland is composed of a great number of similar small masses or lobules, which may be separated by dissection, and are held together by fine cellular tissue continued from that which invests the whole gland. The lobules vary in size from half a line to three lines in diameter, and have simple or complex cavities filled with a milky fluid. Sir Aetley Cooper ('The Anatomy of the Thymus Gland') says that the lobules are arranged in spiral lines, so that the gland may be unravelled into a sort of knotted rope of lobules, which are wound around a central cavity or reservoir, with which the cavities of the lobules communicate. But the existence of such a central cavity is not generally admitted.

The fluid contained in the cells of the Thymus Gland is, in young and healthy animals, opaque and creamy. It has been particularly examined by Mr. Gulliver (Appendix to Gerber's 'General Anatomy'), who has found that both in its chemical composition, and in the abundance and structure of the globules which it contains, it closely resembles the fluid of the lymphatic glands.

Of the function of the Thymus Gland scarcely anything probable is known. Whatever it be, it is performed most actively during foetal life and the first year of extra-uterine life; for during this time the Thymus Gland grows at the same rate as the rest of the body, its cells are full of fluid, and the fluid is thick and abundant in globules. From the end of the first to the end of the third year its size does not materially vary, but after this time it gradually diminishes, and after the twelfth or fourteenth year it is rare to meet with more than a slight trace of it.

THYNNUS. [SCOMBRIDÆ.]

THYONES, or THYONIDÆ, a family of *Echinodermata*, belonging to the order *Holothuriada*. They are characterised by the pyriform shape of their bodies whilst resting, and a cylindrical form whilst moving; they are contractile, and covered all over with numerous papillose suckers; they have 10 branching tentacles. From their elongated character, and their body being covered with suckers, they resemble some forms of *Cactus*, and have hence been called Sea-Cactuses. The genus *Holothuria* is often included in this family. It is distinguished from *Thyone* by possessing 20 tentacles, which are not branched as in *Thyone*.

Thyone is thus characterised:—Body nearly regular, covered with scattered wart-like suckers; tentacles 10; teeth long and thread-like. There are three British species of this genus.

T. papillosa, the Common Thyone, has an elongate-ovate body of a brownish-white colour, with the tentacula much pinnated. It was first found by Dr. Johnston, and has since been taken several times on the British coasts.

T. Portlockii and *T. Raphanus* are the remaining British species.

THYROID GLAND is an organ situated in the middle and fore part of the neck, in front and by the sides of the thyroid cartilage of the larynx (from which it has its name), and of the cricoid cartilage and the upper part of the trachea [LARYNX], to which it is closely fixed by cellular tissue. It is composed of two chief lateral portions or lobes, and a smaller portion or isthmus connecting them. A fourth portion, which is long and slender, and is named the middle column or horn, usually passes upwards from the isthmus in front of the larynx. The lateral lobes are of a somewhat pyramidal form, about two inches long, and an inch wide at their bases. The whole gland is proportionally larger in the embryo than in the adult, and in women than in men.

Of the function of this gland but little is known. It is subject to enlargement in scrofulous states of the system, and this disease is known by the names of Bronchocele and Goltre.

THYSANODACTYLUS. [IGUANIDÆ.]

THYSANOPODA. [STOMAPODA.]

THYSANURA, Apterous Insects, with six legs and peculiar organs of motion on their sides, or at the extremity of the abdomen. They undergo no metamorphosis. They have been grouped by Latreille under two families, of which *Lepisma* and *Podura*, two Linnæan genera, are the respective types. In the first we have a number of brilliant silvery little insects, covered with small scales, which are used as tests for the powers of microscope glasses. They have long setaceous many-pointed antennæ, distinct palpi to the mouth, and movable false feet on the sides of the abdomen; the body is terminated by articu-

lated setæ, three of which are especially conspicuous. The *Podurellæ* have 4-pointed antennæ, indistinct palpi, an abdomen terminated by a forked tail, which is folded under the belly when the animal is at rest, and serves to aid it in leaping. They are little, long, soft insects. The *Lepismenæ* and *Podurellæ* live chiefly among wood or under stones.

TIARA. [VOLUTIDÆ.]

TIARIS. [DRACONINA.]

TIARIS, a genus of *Fringillidæ*.

TIBIA. [SKELETON.]

TIBIANA, a genus of *Polypniaria*.

TICHODROMA. [CERTHIADÆ.]

TICKS. [ACARIDÆ; TRACHEARIA.]

TICO'REA, a genus of Plants belonging to the natural order *Rutaceæ*. It has a small 5-toothed calyx, a monopetalous funnel-shaped corolla with a long tube, and a 5-cleft limb, either equal or unequal. The stamens are from five to eight, of which from two to six are often sterile. The disc is cup-shaped, surrounding the ovary; the stigma 5-lobed.

T. jasmminiflora is a shrub from 7 to 8 feet high, a native of Rio Janeiro. The leaves are ternate and stalked; the leaflets lanceolate, from 1 to 6 inches long, tapering to the base, acuminate, obtuse, deep green with pellucid dots. The calyx is rather downy, the corolla white, downy, glandular, with pellucid dots. A decoction of the leaves is drunk by the Brazilians as a cure for framboesia.

T. febrifuga differs but little in its character from the last species, but in its stem being generally arborescent, its panicles contracted, its flowers not more than half the size, the bracts more numerous and foliaceous, and the style more protruded. The bark is intensely bitter, astringent, and is regarded as a febrifuge.

(Lindley, *Flora Medica*.)

TIGA. [PICIDÆ.]

TIGER. [FELIDÆ.]

TIGER-BITTERN. [TIGRISOMA.]

TIGER-CAT. [FELIDÆ.]

TIGLIUM. [CROTON.]

TIGRIS. [FELIDÆ.]

TIGRISOMA, Mr. Swainson's name for the Tiger-Bitterns. The species have the bill as in *Ardea*; face, and sometimes the chin, naked; legs almost feathered to the knees; inner toe rather shorter than the outer; claws short, stout, regularly curved; anterior scales reticulate or hexagonal. Mr. Swainson considers this to be the rasorial type, and he arranges it as a sub-genus of the family *Ardeadeæ*, between *Butor* (Antig.) and *Nyctiardea*.

TILESIA. [MILLEPORIDÆ.]

TILGATE BEDS. A portion of the great series of strata in the Weald of Kent and Sussex, interposed between the green-sands and the Portland oolite, is thus named by Dr. Mantell, who has described the numerous and interesting organic remains which it contains. (Mantell, *Fossils of the British Museum*.)

TIL'IA, a genus of Plants belonging to the natural order *Tiliaceæ*. The trees in England are called Lime-Trees, in Swedish *Linna*, and in German and Dutch *Linden*. They are characterised by possessing a 5-parted deciduous calyx; 5 petals; numerous free or somewhat polyadelphous stamens; a globose, villous, 1-styled, 5-celled ovary. All the species are handsome trees, with alternate, heart-shaped, acute, serrated, deciduous leaves, and fragrant yellowish panicked flowers. The wood is light, smooth, and white, and the sap possesses a considerable quantity of sugar. They are principally natives of Europe and America.

T. Europæa, the European or Common Lime-Tree, has petals without scales, and cordate acuminate serrated leaves, which are smooth, with the exception of a tuft of hair at the origin of the veins beneath, and are twice the length of the petioles; the cymes are many-flowered, and the fruit is coriaceous and downy. This tree is abundant in the middle and north of Europe. It is very common in Great Britain, although some doubts have been expressed as to its being truly indigenous. It is however admitted into all British Floras; and there can be no doubt, from its wide diffusion, that it is truly naturalised in this country. It was well known to the ancients, and is spoken of by both Theophrastus and Pliny. It is a very general favourite in Europe, and is planted in public places, parks, and approaches to residences, in France, Germany, Holland, and Great Britain. For this purpose its large size, handsome appearance, and profusion of sweet flowers well adapt it. The wood is in considerable request. The Russian mats used by gardeners and upholsterers are made from its bark. The flowers secrete a large quantity of nectar, and exhale a delicious scent. The seed of the lime possesses a large quantity of albumen, which is nutritious and perfectly innocuous.

The Lime-Tree attains a great age; and many specimens, celebrated for their age and size, exist. The principal street of Berlin is called Unter den Linden, from the lime trees which are planted on each side.

Many varieties of this tree are described; and, as is usual in these cases, some authors have elevated them to the rank and importance of species.

T. microphylla, the Small-Leaved Lime, has its petals without nectaries or scales; cordate, roundish, acuminate, serrated leaves, smooth above and glaucous beneath, with scattered as well as axillary hairy blotches, and compound many-flowered umbels. This is identical

with the *T. parvifolia* of Ehrhart and other writers. It is a native of subalpine districts in the north of Europe. In Great Britain it is common in the woods of Essex and Lincolnshire; and Mr. E. Forster thinks it probable that this is the only true British species.

T. rubra, the Red Lime, is a native of Taurida, and some few specimens are growing in England.

T. platyphylla, the Broad-Leaved Lime-Tree, is the *T. grandifolia* of Ehrhart and other botanists. It is more common than the other species in Switzerland and the south of Europe.

All the foregoing species are distinguished by not having nectaries or scales at the base of their petals. There are six other species characterised by possessing nectaries.

T. alba, the White or Silvery Lime; *T. glabra*, the Black or Black American Lime-Tree; *T. laxiflora*, Loose-Flowered American Lime; *T. pubescens*, the Pubescent American Lime; *T. heterophylla*, the White American Lime, are natives of North America; and numerous specimens of them are found growing in our forests and shrubberies.

TILIACEÆ, Lindenblooms, a natural order of Plants belonging to the syncarpous group of Polypetalous Dicotyledons. This order consists of trees or shrubs, seldom of herbaceous plants, with simple, toothed, alternate leaves, furnished with stipules. The flowers are axillary. The calyx consists of 4 or 5 sepals, which are valvular in æstivation; the petals 4 or 5, with mostly a little pit at their base; the stamens are hypogynous, mostly indefinite, with oval or roundish 2-celled anthers bursting lengthwise; the disc is formed of glands, which are equal in number to the petals and opposite to them; the ovary is single, composed of from 4 to 10 carpels, with a single style and stigma divided into lobes according to the number of the carpels; seeds numerous, with erect embryo, and abundant albumen. This order is nearly allied to *Sterculiaceæ* and *Malvaceæ*, from which it differs in its glandular disc, distinct stamens, and 2 celled anthers. The species, of which there are about 250, are arranged in 32 genera, and are generally diffused throughout the tropical and temperate parts of the globe.

Tiliaceæ possess no active properties; they abound in a mucilaginous wholesome juice. The fibres of the inner bark are very tough, and are used for a variety of economical purposes. [*TILIA*.] The wood is generally white, light, and tough; that of *Grewia elastica* is used for making bows in India. The Trincomalee-Wood used at Madras for making the Massoola boats is the produce of *Berrya Ammonilla*. The *Corchorus olitorius* is cultivated in Egypt for use as a pot-herb.

Tilia alba.

1, cutting, with flowers and leaf; 2, section of ovary, showing the cells; 3, single flower; 4, stamens.

TILIQUA. [SCINCIDÆ.]

TILL. [BOULDER-FORMATION.]

TILLÆA, a genus of Plants belonging to the natural order *Crassulaceæ*. It has a 3- or 4-parted calyx; petals 3 or 4, oblong acuminate; scales none, or very small; carpels 3 or 4, somewhat constricted in the middle; 2-seeded. The species are small glabrous annual herbs, inhabitants of exposed subhumid places. The leaves are opposite. Flowers small, white, for the most part axillary.

T. muscosa is a native of Europe in many places, in dry, barren, sandy, and gravelly soil; plentiful in Britain on the most barren sandy heaths, and frequent in Norfolk and Suffolk. It has a stem branched and decumbent at the base; flowers axillary, sessile, and trifid. The plant is very minute, and of a reddish colour. The leaves are

opposite, oblong, obtuse, concave above, connate; sepals ovate or lanceolate acute, bristle-pointed. Petals nearly subulate, white, tipped with red. There are several other species, natives of North and South America and Australia.

TILLANDSIA, a genus of Plants belonging to the natural order *Bromeliaceæ*. Linnæus says of the plants belonging to this genus, "Tillandsia cannot bear water, and therefore I have given this name to the genus from a professor at Abo, who in his youth having an unpropitious passage from Stockholm to that place, no sooner set his foot on shore than he vowed never again to venture himself upon the sea. He changed his original name to Tillands, which means on or by land; and when he had subsequently occasion to return to Sweden he preferred a circuitous journey of 200 Swedish miles through Lapland to avoid going eight miles by sea."

The genus *Tillandsia* comprehends the plants described by Sloane as *Viscum caryophylloides*, and by Plumier as *Caragata*; and is characterised by possessing a persistent calyx divided into three oblong, lanceolate-pointed segments; a corolla tubular, longer than the calyx, with the limb divided into three segments; six stamens not so long as the corolla, and inserted into it, and the anthers sagittate; the ovary superior, surmounted by a style with a trifid obtuse stigma; the fruit, a trilocular capsule containing several seeds, each of which is supported on a long stalk of aggregate fibres, which in the end constitutes a feathery wing. The species are most of them parasitical, and are natives of South America.

T. utriculata, the Wild Pine of the colonists of Jamaica, has linear, channelled, recurved, dilated leaves, inflated at the base; stem closely panicle. It is found growing on old and decaying trees in the forests of Jamaica. The stem is 3 or 4 feet high, and the leaves are a yard long, and placed within one another in such a way that the water which runs down them is retained in their expanded bases. The bases then swell out and form a reservoir or bottle, which, being contracted at the neck, prevents the heat of the sun from evaporating the water. These reservoirs will each hold about a quart of water, and during the dry season they are the resort of all kinds of animals for the sake of the water, and travellers are often able to obtain a supply of water from this source when all others fail.

T. usneoides, the Long-Moss Tillandsia, or Barbe de Vieillard of the French, the *Viscum caryophylloides* of Sloane, has a twisted, thread-shaped, scaly stem, much branched, with channelled leaves. This plant is a native of the forests of North America, from Virginia to Florida, also of the West India Islands and the Brazils. In medicine this plant has been recommended as a remedy in hæmorrhoids, also as an effectual diaphoretic.

T. monostachya, Single-Spiked Tillandsia, has the radical leaves linear, channelled, recurved, broad, and sheathing at the base; the stem simple, clothed with imbricated scales; the spikes simple; the bractæes ovate-concave. This plant is a native of the West Indies. The leaves of this as well as most of the other species serve as reservoirs for water. About 30 species have been enumerated.

TIMALIA (Horsfield), a genus of Birds thus characterised:—Bill strong, compressed, deep (altum). Nostrils subrounded. Wings short, rounded. Tail elongated and graduated. Feet strong; hind-claw twice as large as the middle anterior claw.

T. pileata. Body ovate, rather stout. General colour above, brown with an olivaceous tint; underneath, testaceous inclining to gray. Head capped with saturated chestnut. Throat and cheeks white. Breast white inclining to gray, marked with intensely black stripes by the shafts of the plumes. Bill black and shining. Feet brown. (Horsfield.)

Timalia pileata. (Horsfield.)

Dr. Horsfield observes that the species is not unfrequent in the groves and small woods which abound throughout Java. It often,

he says, approaches villages and plantations, constructing its nest in the hedges; and he speaks of it as one of the social birds that delight to dwell in the vicinity of cultivation. In large forests he did not notice it. He describes its flight as low and interrupted, and adds that wherever it resides it is a welcome neighbour, in consequence of the peculiarity and pleasantness of its note, which consists of a slow repetition of the five tones of the diatonic scale (C, D, E, F, G), which it chants with perfect regularity, several times in succession, and at small intervals of time. Dr. Horsfield further remarked that the sixth tone was sometimes added; but as this required apparently an extraordinary effort, it was by no means so agreeable to a musical ear as the simple repetition of the five notes, which appeared to be the natural compass of the bird's organs. ('Zoological Researches in Java.')

TINALINÆ, a sub-family of Birds belonging to the *Turdida*. [TIMALIA.]

TIMOTHY GRASS, the common name for the *Phleum pratense*. [PHLEUM.]

TIN. This metal is one of those which were earliest known, though it occurs in comparatively few countries. The acquaintance of the ancients with this metal, though it does not occur in the native state, is accounted for by the circumstances that the ore is found frequently near the surface, and is easily reduced by charcoal and a moderate degree of heat to the state of metal.

According to Berzelius Tin is found in England, Saxony, Bohemia, Hungary, the Isle of Banca, the Peninsula of Malacca, in Chili, and Mexico. Malacca furnishes the purest tin, and Cornwall the largest quantity.

Tin occurs in two states of combination, the peroxide and double sulphuret of tin and copper: this last is rather a rare substance, and it is from the former that the metal is almost entirely obtained.

The Peroxide of Tin is found in Cornwall in two forms:—1. In veins in primitive countries, where it is intimately mixed with several other metals, as arsenic, copper, zinc, and tungsten: this is common *Tinstone*. 2. In loose rounded masses, grains, or sand in alluvial soil, in which state it is called *Stream-Tin*. The former, when reduced to the metallic state, yields *Block-Tin*; while the latter yields *Grain-Tin*, which is the purer of the two.

Oxide of Tin—Tinstone—occurs in attached and imbedded crystals, and massive. Primary form a square prism, which is commonly terminated by four-sided pyramids. Cleavage parallel to the lateral planes and both diagonals. Fracture uneven or imperfectly conchoidal. Hardness 6 to 7: gives sparks with steel, and is brittle. Colour white, yellow of various shades, red, brown, and black. Streak paler. Lustre adamantine, vitreous. Transparent, translucent, opaque. Specific gravity 6·86. Insoluble in acids. Before the blow-pipe, in powder on charcoal, it is reduced to the metallic state. Fine crystals of this substance occur, more especially in Cornwall and Saxony.

The analysis of the Oxide of Tin of Cornwall by Klaproth gives—

Tin	77·50
Oxygen	21·50
Iron	0·25
Silica	0·75

—100

The Massive Varieties of Oxide of Tin are called *Stream-Tin*. What is termed *Wood-Tin* is found in reniform and botryoidal masses, or in wedge-shaped pieces, which have arisen from their partial destruction: the surfaces are generally water-worn. *Wood-Tin* exhibits various shades of brown, which sometimes appear in concentric bands, giving it a ligneous appearance, whence its name.

Stream-Tin has evidently been derived from the destruction of tin veins or lodes, the lighter portions of stony matter having been carried away by the water, which has rounded the fragments of the ore.

At Finbo in Sweden Oxide of Tin has been met with containing nearly 2½ per cent. of Oxide of Columbium.

Tin Pyrites—Sulphuret of Tin, a double Sulphuret of Tin and Copper—is a rare substance, having been found only in Cornwall at Huel Rock, in the parish of St. Agnes.

It occurs crystallised and massive. Primary form of the crystal a cube. Cleavage parallel to the faces of the primary form. Fracture uneven, with a metallic lustre. Hardness: readily scratched and reduced to powder; brittle. Colour steel-gray, mixed with yellow. Specific gravity 4·35.

Massive Variety.—Fracture granular and uneven, with a metallic lustre. Hardness 4. Brittle. Opaque. Specific gravity 4·35 to 4·76.

The following analysis by Klaproth gives—

Tin	34
Copper	36
Iron	2
Sulphur	25

—97

TIN PYRITES. [Tin.]

TINACTORI. [MERULIDÆ.]

TINAMOU, a genus of Birds belonging to the family *Tetraonidæ*.

T. Tataupa, is a native of South America.

Tinamus Tataupa, var. (Swainson.)

Mr. Darwin, in his graphic description of the country around Maldonado, gives the following account of this bird:—"The country wore the same aspect, till at last the fine green turf became more wearisome than a dusty turnpike-road. We everywhere saw great numbers of partridges (*Tinamus rufescens*). These birds do not go in coveys, nor do they conceal themselves like the English kind. It appears a very silly bird. A man on horseback, by riding round and round in a circle, or rather in a spire, so as to approach closer each time, may knock on the head as many as he pleases. The more common method is to catch them with a running noose or little lazo, made of the stem of an ostrich's feather, fastened to the end of a long stick. A boy on a quiet old horse will frequently thus catch 30 or 40 in a day. The flesh of this bird, when cooked, is delicately white." ('Journal of Researches in the Countries visited by H. M. S. Beagle.')

TINCA, a genus of Fishes founded by Cuvier, and which has for type the Common Tench (*Cyprinus Tinca*, Linn.).

T. vulgaris, Cuv., the Tench, belongs to the Carp family (*Cyprinidæ*), and is separated generically on account of the small size of the scales with which the body is covered, combined with the small antero-posterior extent of the dorsal and anal fins, both of which are destitute of the anterior bony spine or any such as are observable in some allied fishes—as in the dorsal fin of the Barbel for instance. The barbules to the mouth are very small.

The Tench, observes Mr. Yarrell, inhabits most of the lakes of the European continent. In this country, though frequent in ornamental water and ponds, it is but sparingly found in the generality of our rivers. There is some doubt whether, like the carp, its origin be not foreign, and whether those rivers that can now boast of it are not indebted for it to the accidental escape of fish from the preserved waters of neighbouring gentlemen. The rivers it is mostly in are those which are slow and deep, and in such situations it does not appear to be so prolific as in ponds. Cuvier observes that the tench inhabits by preference stagnant waters. This is in accordance with the observations of Mr. Yarrell, and rivers being an unnatural habitat for the fish, will account for their being less prolific in such situations.

It is very tenacious of life. "A piece of water which had been ordered to be filled up, and into which wood and rubbish had been thrown for years, was directed to be cleared out. Persons were accordingly employed; and, almost choked up by weeds and mud, so little water remained, that no person expected to see any fish, excepting a few eels, yet nearly 200 brace of tench of all sizes, and as many perch, were found. After the pond was thought to be quite free, under some roots there seemed to be an animal which was conjectured to be an otter; the place was surrounded, and on opening an entrance among the roots, a tench was found of most singular form, having literally assumed the shape of the hole, in which he had of course for many years been confined. His length from eye to fork was 33 inches; his circumference, almost to the tail, was 27 inches; his weight 11 lbs. 9½ ounces; the colour was also singular, his belly being that of a char, or vermillion. This extraordinary fish, after having been inspected by many gentlemen, was carefully put into a pond, and at the time the account was written, twelve months afterwards, was alive and well." (Yarrell.)

Experiments have shown that a tench is able to breathe when the quantity of oxygen is reduced to a five-thousandth part of the bulk of the water: ordinary river water generally containing one per cent. of oxygen.

The general colour of the tench is greenish-brown, or olive having a golden hue, which latter tint is most conspicuous on the under parts of the fish. From the carp it is readily distinguished by the small

size of its scales, and also the small extent of the dorsal fin: its form is rather less deep in proportion to the length. It spawns usually about the middle of June, and deposits its ova on weeds.

TINCAL. [BORAX.]

TINEIDÆ, a family of small Moths, which are remarkable for depositing their eggs among animal substances, on which their larvæ afterwards feed. They are thus constantly found upon clothing made of hair or fur, and are called Clothes-Moths. The family is thus defined:—Antennæ moderate, slender, simple, pubescent beneath in the males; proboscis short; thorax rarely crested; body long and slender; wings entire, often narrow, mostly convoluted in repose. The caterpillars live in portable cases formed of various materials.

These moths are often ornamented with very brilliant colours, the upper wings having gold or silver spots. The caterpillars make their cases of the substances on which they feed. The *Adela* make their nests of bits of leaves. The true *Tinea* clothe themselves with the hair of the skins of animals and bits of silk. When too small, they slit their cases and make them larger. Many of them burrow into skins, silk garments, &c., making cases as they proceed. The genera and species are very numerous.

(Westwood, *Entomologist's Textbook*.)

TINNUNCULUS, a genus of Birds belonging to the family *Falconide*.

T. alaudarius, the Kestrel, may be taken as the type of this genus. This is, there can be little or no doubt, the *Κεραυρος* of Aristotle ('Hist. Anim.,' ii. 17; vi. 1; vii. 3), and so most zoologists are disposed to consider it, as well as that it is the *Tinnunculus* of the Romans. (Pliny, 'Nat. Hist.,' x. 37.) It is the Fontivento, Canibello, Tristunculo, Acertello Falchetto di Torre, Gheppio, and Gavinello, of the Italians; Cerecelle, Quercerelle, Cresserelle, and Epervier des Alouettes, of the French; Turmfalke, Röthel-Geyer, Mausefalk, Windwacht, Rittlweyer, and Wannen-Weher, of the Germans; Kyrko-Falk of the Swedes; Kestrel, Stannel, Stonegall, and Windhover, of the English; and Cudyll Coch of the Welsh.

This bird is found in Europe generally, but not habitually beyond the regions of the arctic circle, where its place is occupied by the Merlin. England, Scotland, and Ireland. Smyrna, in winter at least (Strickl.). Africa, from the north to the south, according to Temminck. Senegal, according to the same authority. The Zoological Society have received it from the Cape of Good Hope; Asia, India (Selby); banks of the Ganges (Yarrell); Java (Horsf.); Japan (Siebold and Bürger). Mr. Yarrell states that figures of it occur in drawings from China.

Kestrel (*Tinnunculus alaudarius*), male and female. (Gould.)

The provincial name Windhover well expresses the most striking characteristic of this hawk. With its head to windward, whence Mr. Mudie suggests that one of its designations should be written 'Stand-

gale,' not 'Stonegall,' it remains with outspread tail and winnowing wings suspended high in air, so that its piercing eye may include a considerable area, in which no field-mouse is safe: when the bird sees one, it drops unerringly on the surprised prey. When thus poised above the fields, it sometimes is within the range of a gun, and we have heard farmers exult in bringing one down, little thinking that the bird was then on the watch for one of their greatest enemies.

If a Kestrel can find the nest of a crow or a magpie as a receptacle for its eggs, it will not take the trouble to make one; indeed, it probably never does build: sometimes it lays upon the bare ledges of rocks and in old ruined towers. The number of eggs is four or five, and their ground-colour reddish-white, which is mottled closely with dark reddish-brown and sometimes blotched with reddish-brown. The young come forth from the egg towards the end of April or beginning of May, and are covered with a yellowish-white down.

In the 'Portraits d'Oyseaux,' the following quatrain sums up the qualities of the Kestrel:—

"Mulots, Lezars, Rats, et autre vermine,
Sont la viande à nostre Cresserelle.
Elle est amye avec la Colombeille,
Qu'elle deffend des oyseaux de rapine."

The allusion here made to the friendship of the Kestrel for the Dove, is probably taken from the passage in Pliny to which we have above referred.

TINSTONE. [Tin.]

TIPHIA. [SCOLIAIDÆ.]

TIPULA. [TIPULIDÆ.]

TIPULIDÆ, a family of Dipterous Insects belonging to the tribe *Nemocera*. They have the antennæ longer than the head, simple, not plumose, rarely pectinated; eyes entire, ocelli obsolete; front of head beaked; proboscis short, ending in two large fleshy lips; body elongated; wings long, nervures numerous; legs long.

The types of this family are the species of *Ctenophora*, *Pedicia*, and the species of *Tipula* which are usually known by the name of Daddy-Long-Legs.

Latreille divides this family into five smaller groups—Culiciformes, Gallicoles, Terricoles, Fungivores, and Florales.

The Culiciformes (*Chironomides*, Macquart) include those forms the pupæ of which mostly dwell in the water, respiring by means of external tubes or filaments situated in front of the body. They have also the power of swimming. Many of them are transparent, and form exceedingly beautiful objects for the microscope. The larvæ of *Chironomus plumosus* are vermiform, and of a blood-red colour, whence they are called Blood-Worms. [CHIRONOMUS.]

The Gallicoles (*Cecidomyides*) include those species which form galls by depositing their eggs upon plants. [CECIDOMYIA.]

The Fungivores (*Mycetophilides*, Macquart) embrace an extremely active group of these insects, which are capable of leaping by means of their hind legs. They are found in damp situations amongst various plants. They enter houses, and are found upon window-paues. They are also very partial to *Fungi*, hence their name; and they are generally found in the interior of *Boleti* and *Fungi*.

The Terricoles (*Tipulides*, Macquart) are the true Crane-Flies. The species of the genus *Tipula* are found in damp meadows in great numbers, especially in the autumn. The larvæ are found in the soil, and feed upon the roots of grass, &c., and occasionally they do much harm. Mr. Westwood remarks that the male Daddy-Long-Legs is very quarrelsome, and often fights with his brethren of the same species.

The Florales (*Bibionides*, Macquart) are distinguished by having the body and legs shorter and more robust than the other forms. The species are small, and their flight is slow and heavy.

(Westwood, *Families of Insects*.)

TISSUES, ANIMAL. The ultimate parts of the organs of animals and plants, of which their bulk is composed, are called Textures, or Tissues. These parts are found to originate in cells, and to have their characters principally given to them by the growth and development of these ultimate constituents of all organised beings. An account of the Tissues thus formed will be found under the articles ANATOMY; AREOLAR TISSUE; ADIPOSE TISSUE; BONE; BLOOD; CELLS; CARTILAGE; GLANDS; MUSCLE; NERVOUS SYSTEM; INTESTINES; SKIN; TEETH.

TISSUES, VEGETABLE. The tissues or textures of plants are formed out of cells which have grown together in various ways. [CELLS.] Although the most general form of the cell is that of a sphere, by pressure and growth in various directions it assumes a variety of shapes, when several together enter into the composition of a tissue. This is more remarkably the case in the animal than in the plant.

In many parts of plants the cells are perfectly spherical, arising from the absence of pressure. It more frequently happens however that cells press each other regularly in all directions, when they assume a polyedral or many-sided form. (Fig. 1, a, b.) When the pressure is perfectly regular the figure assumed is that of a dodecabedron, and when cut through each section presents six sides. All kinds of departures from this normal form are constantly seen. In these cases the nutrition is regular in every part of the cell. In the cells of

exogenous and endogenous plants there is a constant tendency to the nutrition of the cells at either end, so that an elongated cell is thus formed. These cells are sometimes called vessels, and constitute the basis of what is called Vascular Tissue. Several cells may join together, and the intermediate parts of their walls being absorbed, they form a long tube or vessel. This is the way in which the longer and larger forms of vascular tissue are probably formed. (Fig. 4, d, e, f, g, h, i.) Sometimes this nutritive manifests itself in more than two directions; we then have what are called Stellate Cells. These cells are seen beautifully in the common rush, and all sorts of modifications of them are seen in water-plants, where the interstices between the projecting and united parts of the stellate or irregular cells are filled with air.

Cells grow or develop in two ways. First, by taking up the nutritive matters into the cell-wall, which thus becomes enlarged; second, by the deposit of new materials in the inside of the cell-wall. In the cases above referred to the forms produced are the result of growth by intussusception, but in a large number of cases the cells and vessels of the tissues become curiously ornamented by deposits in their interior. The most frequent form which these deposits take is that of a spiral fibre (fig. 1, d), which is found in the interior of the cells or vessels. This deposit may be so regular as to form a fibre, which may be separated from the walls of the cell; but more frequently it happens that these deposits assume the form of rings, dots, bars, or even pores. (Figs. 2 and 4.) They have thus given names to various kinds of tissue.

In all these cases the interior protoplasm, endoplast, or primordial utricle, seems to be the seat of nutritive activity. Our knowledge of the movement of the contents of the cells of plants is no longer confined to a few isolated cases, but has been observed in so large a number of cases as to lead to the inference that it is universal. It is also known that many of the currents observed assume a spiral direction, and it has been inferred that the spiral deposits are the result of such currents acting in the cells. The recent observations of Branson and Wenham have also shown that these currents are due to the active molecular movements that occur in the primordial utricle of the cell in which the movements have been observed.

One of the most interesting forms of nutrition is the case in which the active endoplast of protein projects beyond the cell-wall, and forms upon its surface a moveable hair-like projection, to which the name Cilium has been given. These cilia are the causes of the active locomotion observed in many of the spores of the *Alga*, and of such compound unicellular plants as *Volvox globator*. [CILIA; VOLVOGINEÆ.]

The tissues of plants formed in the manner above referred to assume a variety of appearances, and vegetable physiologists have accumulated a large number of terms to express them. The following sketch will however give an idea of the general forms they assume:—

I. CELLULAR.

Tissue composed of membrane in the form of cells whose length does not greatly exceed their breadth.

A. Parenchyma.

Tissue composed of cells.

1. Incomplete.
2. Complete.

B. Inter cellular System.

Tissue in which cells are absent.

1. Original cavities.
2. Cavities subsequently formed.

C. Epidermal System.

Tissue on the surface of plants.

1. Epidermis.
2. Appendicular Organs.
 - a. Papillæ.
 - b. Hairs.
 - c. Setæ.
 - d. Stings.
 - e. Prickles.
 - f. Warts.

II. FIBRO-CELLULAR.

Tissue composed of cells, in the inside of which fibres are generated.

- a. Genuine.
 1. Fibrous cells.
- b. Spurious.
 2. Pore cells.
 3. Dotted cells.

III. VASCULAR.

Tissue composed of cylindrical tubes of membrane, continuous, or overlying each other at their ends.

1. *Pleurenychyma*, with the sides of the tubes thickened and tapering to each end.
2. *Cinenchyma*, the sides of the tubes of which anastomose, and convey a peculiar fluid.

IV. FIBRO-VASCULAR.

Tissue composed of tubes, in the inside of which one or more spiral fibres are more or less perfectly developed.

a. Genuine.

1. Spiral vessels.
2. Annular vessels.
3. Moniliform vessels.

b. Spurious.

4. Scalariform vessels.
5. Porous vessels.
- (*Bothrenchyma*.)
6. Dotted vessels.

We shall now proceed to give a short description of the principal forms these tissues assume.

Cellular Tissue; also called Utricular and Vesicular Tissue; the Parenchyma of Lindley and Morreu, and others, *Tela Cellulosa* of Link, and *Contextus* and *Complexus Cellulosus* of older writers; *Zellgewebe*, German; *Tissu Cellulaire*, French.—This tissue consists of cells or cavities, which are closed on all sides, and are formed of a delicate mostly transparent membrane. It is present in the whole vegetable kingdom; and all the lower forms of plants, constituting the class *Thallogens* (Lindley), are composed entirely of it, and have hence been called *Cellulares*. In the higher plants it is most abundant in fruits and succulent leaves. It exists in larger quantity in herbs than trees, and the younger the plant is the more it abounds, and constitutes the entire structure of the embryo.

The normal form of the cells is spheroidal, and when they exist in this or in an elliptical form, and only touch each other at a few points without exerting pressure, they constitute the tissue called by Meyen *Merenchyma*. The cells in this case may form a regular or irregular layer, a distinction which may be of some importance. Such tissue is found in many parts of plants, especially those which are delicate and easily torn, as in the pulp of fruits like the strawberry, in the petals of the white lily, in the stem of *Cactus pendulus*, where they are spheroidal, and in the leaf of the *Agave Americana*, where they are elliptical. The cells also which constitute the entire of many of the lower plants belong to this division of cellular tissue. They are seen separate or loosely adhering to each other in the *Proteococcus nivalis*, the plant of the Red-Snow (SNOW, RED), in many of the smuts and brands, as *Ustilago* and *Uredo*. *Chroolepus*, and many of the lower forms of *Alga* and *Fungi*, consist of filaments which are entirely composed of spheroidal cells arranged one upon another.

In the higher forms of plants the vegetative force is greater, and a greater number of cells being generated in a given space, they press on each other on all sides, assuming a variety of forms, and constituting the tissue called by Meyen *Parenchyma*. The principal varieties of *Parenchyma* distinguished by Meyen are:—

1. The Cubical, which exists in the cuticle of some leaves, and is not unfrequently met with in bark and pith, as in the pith of *Viscum album*. (Fig. 1, c.)

Fig. 1.

2. The Columnar, of which there are two varieties: the Cylindrical (*Cylindrenchyma* of Morreu), examples of which may be seen in *Chara* and in *Agaricus muscarius*; the Prismatical (*Prismenchyma*), frequently seen in the pith and the bark of plants, and when compressed it becomes the muriform tissue (fig. 1, e), which is constantly found in the medullary rays, and has its name from the cells being arranged as bricks in a wall.

3. The Dodecahedral: the natural form of parenchyma when the cells are of equal size and exert on each other equal pressure, and when present a hexagonal form. (Fig. 4, a, c.)

4. The Stellated (*Aetenchyma*), in which the cells, from the irregularity of their walls, assume a star-like form, seen in *Musa*.

5. The Tabulated, seen in the epiphleum of many plants: other forms, as Conical (*Conenchyma*), Oval (*Ovenchyma*), Fusiform

(Atractenchyma), Sinuous (Colpenchyma), Branched (Cladenchyma), Entangled (Dadalenchyma), have been described by Morren.

Prosenchyma differs from Parenchyma in the cells always having an elliptical form which taper to their extremities, where they overlap each other. This form of tissue is found only in the bark and wood, and is a transition from cellular to what is called woody tissue. Meyen applies this term especially to the tissue forming the wood of *Coniferae* and *Cycadaceae*. In these families this tissue is marked with dots, which are surrounded by a circle (fig. 2). These dots were formerly supposed to be glands, and to secrete the resinous matter which abounds in them, and hence it was called 'glandular woody tissue.' The researches of Mohl and others have however shown that these dots are the result of the development of fibre within the walls of the cells, and in this view the Prosenchyma not only constitutes a transition from cellular to vascular tissue, but also a transition from fibro-cellular to fibro-vascular tissue.

Fig. 2.

It is mostly in the interior of the cells of cellular tissue that those crystalline bodies called Raphides are found. They occur singly or in bundles, and have an acicular form, and are long or short according to circumstances. In length they measure from 1-40th to 1-1000th part of an inch. These crystals were first observed in the proper juices of plants, and have been subsequently found in all parts of plants where cellular tissue exists. They were formerly supposed to exist between the cells, but later observers have seen them in cells, and they probably exist in both situations. The form of these bodies is not satisfactorily determined. Mohl describes them as right-angled four-sided prisms vanishing into points. Quekett, who is one of the latest observers on this point, says they are decidedly four-sided prisms, but not always right-angled. Those which are conglomerated are called crystal-glands (krystal-drüsen) by Meyen. They seldom present more than the pyramid of each little crystal composing them. The proportion in which they exist in plants is sometimes very great. In some species of *Cactaceae*, according to Quekett, the crystals equal the weight of the dried tissue. One hundred grains of Turkey rhubarb-root yield between 30 and 40 grains of Raphides; the same quantity of tissue of *Scilla maritima* yielded 10 grains. In most plants these crystals are composed of either oxalate or phosphate of lime. Raspail says the crystals of the oxalate of lime are four-sided prisms with pyramide of the same base; those of the phosphate, six-sided prisms. In *Chara* crystals of carbonate of lime occur in great abundance on the outside of the tissue, and we have observed them in the intercellular passages immediately under the epidermis, but they do not occur in the interior parts of the plant. Schübler found that the crystal-glands of *Hydrurus crystallophorus* consisted of carbonate of lime, and Saigey and De la Pösse found silica in the crystals of the *Mirabilis Jalapa*. Silica is a very prominent constituent of the *Graminaceae*, but is seldom found crystallised. It gives the hardness to the epidermis of the Dutch Rush, and is secreted in large quantities in the joints of the stem of the Bamboo, and is used as an article of commerce under the name of Tabasheer. From the variable form of the crystals in plants it may be inferred that other salts form them besides the above. These bodies do not appear to be necessary parts of the tissues in which they occur, and they have been compared by Link to Calculi and other concretions in the animal kingdom. This view is rendered very probable by the fact that they are always composed of those elements which the plants take up from the soil as necessary nutriment. Meyen has pointed out the fact that plants growing near the sea will throw off the superabundance of chloride of sodium in their tissues in the form of crystals; and we have found crystals of carbonate of lime most abundant in *Chara flexilis*, where the water in which it grew contained most of that substance. Phosphate of lime is necessary to the nutrition of many plants, and the elements of oxalic acid exist in the sap of all plants; and when these are in greater abundance than the vital energies of the plant can appropriate, the laws of chemical affinity come into play, and crystallisation is the result.

The Intercellular System.—The walls of the loose spheroidal cells in Merenchyma consist of a single membrane, but the walls of the more closely-pressed cells of Parenchyma consist of two membranes, originally distinct, but fused into one by growth. It frequently happens that the walls of the cells are not accurately applied to each other, and consequently spaces of various kinds occur between the cells. These are called Intercellular Passages. They occur in the greatest abundance in the loose Merenchymatous Tissue. When these passages exist between the walls of two cells whose sides are united in their middle and recede towards their margins, they are called by Link Mentus Intercellulares. These are most frequently met with in the epidermis of plants. Where the passages are formed of three or more cells the sides of whose walls do not touch, they are called Ductus Intercellulares. These are very well seen in the parenchyma of the stem of the Iris and Hyacinth, and *Heracleum*. These passages have been supposed by De Caddolle and others to convey the sap; but this has probably arisen from an error in observation, as they are easily filled with sap when cut through.

Another kind of Intercellular Formation are the Air Cells (the Lacunae Intercellulares of Link), which are large cavities formed in the tissue of plants, and whose walls are entirely formed of cellular tissue. They may be very distinctly divided into two kinds, the regular and the irregular. The regular exist under the epidermis of many plants, and vary in size, but have in all cases a regularity of structure, their sides being formed of equal-sized cells of cellular tissue. They may be seen in the leaf-stalk of *Calla Ethiopica*, the stem of *Ananthe Phellandrium*, and the petioles of *Nymphaea*. They are very common in water-plants. They are always filled with air in these plants, and serve as a means of buoying them up in the water. The irregular air-cells (Lacunae of Link), are found in old plants; they arise from the growth of the plant tearing asunder the cellular tissue, or from a deficient development or even the absorption of this tissue in particular directions. They may be seen in the stem of the fronds of the *Aspidium Filix Mas*, of *Hippuris*, and *Equisetum*, and in nearly the whole of the family *Umbelliferae*.

All plants are covered with a layer of external cells, which are separated from the adjoining tissue and may be often peeled off in a layer. This is called Epidermis, and consists mostly of one row, but sometimes of two rows of cells, which are generally smaller and denser than those of the surrounding tissues. It is in these cells that the openings occur which are called Stomates. [STOMATES.]

Schleiden divides the epidermis into three forms, which he calls Epithelium, Epiblastema, and true Epidermis. The epithelium is that form of epidermis which is continued into the interior of the organs of plants, as in the inside of the fruit. Epiblastema is applied to that modification of the tissue which is found on the surface of the leaves and other parts of aquatic plants. The true epidermis is found on the outside of the stem, branches, leaves, and other organs of plants.

The epidermal cells are often elevated above the surface. When three or four, or more, form a small projection, it is called a Papilla; when it is longer it is a Hair [HAIRS]; when it becomes harder it is a Setum, and when hard and pointed a Prickle. Warts are still larger excrescences of the epidermis.

Fibro-Cellular Tissue, or Inenchyma, consists of cells formed of membrane, in the inside of which fibre is developed. This tissue may be divided into two kinds, genuine and spurious; the genuine being that in which the fibre is distinctly marked on the inside of the cell, and the spurious that in which the fibre, either by absorption or the union of its various parts, forms rings, bars, dots, and other appearances on the sides of the cell. The genuine fibro-cellular tissue is mostly found in parenchymatous and prosenchymatous cells. It has been known for a long time amongst botanists, and was first described by Hedwig, who was followed by Moldenhawer and others. It is abundant in the external parchment-like layers of the aerial roots of *Orchidaceae*, and has been described in *Oncidium altissimum*, *Acropera Loddigesii*, *Brassavola cordata*, &c. It occurs in the hairs of the pericarp of many of the *Compositae*, as in *Perdicium taraxaci*, *Senecio flaccidus*, and *Trichocline humilis*. Horkel has described it in the epidermis of many *Labiatae*, as *Ziziphora*, *Ocimum*, and many *Salviae*. The seed-coats of many plants possess it, as *Gilia Ipomopsis*, *Polemonium Cantua*, and *Calcaria*; and Kippist has demonstrated its presence in many of the species of *Acanthaceae*. In some of these cases, and many others might be mentioned, the fibre appears to constitute the whole of the cell, and this has led to the supposition that it is found independent of the cell-wall or cell-contents.

The fibre in these cells varies in its position and form. In the cells of the leaf of *Oncidium altissimum* they are very distinct, and occasionally branched. In the testa of the seed of *Maurandya Barclayana*, where they were first pointed out by Lindley, the fibres run in different directions over each other, forming a network. In the endotheium of *Calla Ethiopica* they are parallel, and in this form are very common in the same organ of other plants. In the endotheium of *Nymphaea alba* the fibres form regular arches arising from a plane base. In the elaters of *Jungermannia* and in the testa of *Acanthodium* the cells are greatly elongated, with a single spiral fibre in their interior.

The spurious fibro-cellular tissue includes the Porous and Dotted Cells of many authors, the Cellulae Porosae et Punctatae of Link. In a portion of the parenchyma of *Viscum album* we examined, the inside of the cells will be found to possess a number of bright spots. They were first discovered by Treviranus in *Cycas revoluta*, and supposed by him to be granules. They were thought by other observers to be pores; hence their name Porous Cells. These spots however are not pores, but depressions, produced by the breaking up of the spiral deposits in the interior of the cell.

A transition from porous cells to porous tubes is seen in the tissue which has been called Bothrenchyma. In this tissue, which can be well seen in *Phytocrene*, as well as *Cycas*, a number of truncated porous cells are placed one on the other so as to form a cylinder, which becomes a tube by the absorption or removal of the cellular partitions. Porous vascular tissue is referred to this form by Lindley under the name of Continuous Bothrenchyma, as the partitions or union of the cells are not visible. Where the points of union of the cells are evident, he calls it Articulated Bothrenchyma.

Dotted Cells have their walls marked with dark spots. These cells have been observed in the pith of *Calycanthus floridus* and in the stem of *Dracana terminalis*. They appear only to differ from the porous

cells in the matter from which they are formed having greater opacity, and not transmitting the light so freely.

Vascular, or Tubular Tissue, consists of continuous tubes of simple membrane, and comprehends the woody and the laticiferous tissues. On the one hand they are distinguished by their length from the forms of cellular tissue, and on the other hand by their plane membrane from those tissues of which fibre forms a constituent element.

Pleureenchyma, or Woody Tissue (*Vasa Fibrosa* of Link, and *Fasergefäße*, German), is found abundantly in the wood, and especially the liber, of all plants. It is composed of very long, thin, tough, transparent, membranous tubes. No hairs or dots are seen in their walls, although when they cross each other the points at which they touch may be taken for such markings. They taper acutely to each end, and do not appear to have any communication one with the other, although they are occasionally seen with open extremities, which Slack supposes to arise from the breaking off of one fibre where it was united to another. In the wood and bark of Dicotyledonous Plants they are frequently mixed with Prosenchyma, and in Monocotyledonous Plants with Parenchyma. They grow by increasing in length both above and below. Their diameter varies from 1-150th to 1-3000th of an inch. The walls increase in thickness by the deposition of cellulose. Their form is mostly cylindrical, but in *Cycas revoluta* Link has observed them assuming a prismatic form.

The tubes of woody tissue are very tough, and will resist considerable force without breaking. It is on this account that they are used extensively in the manufacture of cloths of various kinds. The plants used most commonly for this purpose are the hemp and flax. The fibres of *Tilia*, *Daphne*, *Lagetta*, and of many of the plants of the order of *Malvaceæ*, are used for making mats, cordage, whips, &c. The following is a comparative statement of the relative strength of silk and some woody fibre:—

Silk supported a weight equal to	34
New Zealand Flax	23½
Hemp	16½
Flax	11½
Pita Flax (<i>Agave Americana</i>)	7

Woody tissue gives firmness and tenacity to the plant, and assists in conveying the sap from the roots to the leaves.

Vascular Tissue occurs in bundles, that is, several tubes lie close together in a bundle, and are surrounded by cellular tissue. Schleiden describes three kinds of bundles:—1. Simultaneous, in which all the fibres are developed at the same time, as seen in the Ferns. The next are successive, in which the centro fibres are first developed, and those in the circumference after. These are divided into—2. Definite, in which the bundles, after having grown, are closed around by cellular tissue, as are seen in Monocotyledons. 3. Indefinite, in which the bundles do not cease to develop in the direction of their growth, as occurs in the bundles of woody tissue found in the stems of Dicotyledonous or Exogenous Plants. The mode of growth of these two last forms of vascular tissue seems to determine the forms of Monocotyledonous and Dicotyledonous stems.

Cinenchyma, or Laticiferous Tissue, consists of tubes which are mostly branched and anastomosing; their walls are exceedingly delicate in young plants, and thicker in old ones; and they are characterized by conveying a fluid called the latex, which differs from the sap in

Fig. 3.

other parts of the plant. The older botanists, Spigelius, Malpighi, and Grew, described them, but they were generally confounded with woody tissue, till they were investigated by Schultes. In older writers they are called *Vasa Propria* or *Peculiaria*; by Link, *Vasa Opophora*.

They are regarded by many observers as intercellular passages, in the course of which organic matters have been deposited, giving them the character of vessels with walls. The phenomena described by Schultes are most easily seen in plants containing a milky juice, as the *Euphorbiaceæ*. Their most remarkable character is the possession of branches communicating with each other, thus giving them the appearance of the capillaries in animals. (Fig. 3). The

history of their development is not yet sufficiently made out to give them a claim to be considered as a genuine form of vegetable tissue.

Fibro-Vascular Tissue, or Tracheenchyma (*Vasa Spiroidea* of Link), consists of tubes, in the inside of which spiral fibres are generated. The fibres of this tissue are subject to metamorphosis, the consequence of which is, the tubes present the appearances of rings, bars, and bright and dark spots.

The tubes consist of a very delicate membrane, which is mostly cylindrical; it may however assume a prismatic form when the tubes are in bundles and closely pressed together, as in Ferns and many Monocotyledonous Plants. The fibres generated in this tissue are mostly compressed, and wind up the sides of the tube in a spiral form.

When the membrane is broken, the fibre in most cases may be unrolled. It is in the younger tubes that this is most easily effected; as in the older tubes those changes go on which connect the membrane and the fibre firmly together, and convert the latter into bars, dots, &c. The number of fibres included in a tube varies; it is frequently single, but in some instances as many as 22 have been counted. They have no fixed direction; some pass from right to left, others from left to right. Some difference of opinion has existed as to whether the fibres are tubular or not. Schleiden says in most instances they are solid, but where they are formed from large globules of jelly they appear to be tubular in both vascular and cellular tissue.

Link divides fibro-vascular tissue into genuine and spurious; the former includes all those vessels which possess perfect fibres. The principal forms of these are the spiral, annular, and moniliform vessels. The spiral vessel consists of a tube, in which one or more fibres run continuously along its sides from one end to the other (fig. 4, d, e, f.) When the fibres are single, they are called simple; when there is more than one, compound. The spiral vessels are most abundant in young plants, as their character becomes changed by age. When the fibres adhere to the sides of

Fig. 4.

the membrane, they are said to be closed. The spiral vessel was at one time considered a very important tissue, performing especial vital functions. From the circumstance of air being frequently found in them, and this air containing a larger quantity of oxygen than the atmosphere, they were supposed to carry on the function of respiration.

Annular Vessels or Ducts consist of tubes with perfect rings of fibre on their sides. (Fig. 4, g.) These are evidently formed from the interruption of the spires, and the union of the broken ends, as they are frequently found present with a spiral fibre in the same tube. They are mostly larger than the spiral vessels, and the fibre is also thicker: they are very abundant in Monocotyledonous Plants; amongst Dicotyledons they are found chiefly in quick-growing plants, as *Cucurbitacea*.

Moniliform Vessels have successive dilatations and contractions of the tube, and a perfect spiral fibre in their inside. It has been proved by Slack that these vessels derive their peculiar form from accidental compression. They are found in the knots of trees where branches are given off: in roots and other parts where they meet with obstacles to their longitudinal development.

Spurious Fibro-Vascular Tissue includes Scalariform, Poreous, and Dotted Vessels. The spurious vessels are not found in the tissues of young plants, and are either developed after the appearance of the genuine spiroids, or are formed from them.

Scalariform Vessels consist of tubes mostly prismatic, with spots on their walls resembling bars or straps. These bars are placed one above another in a ladder-like form; hence their name. They are abundant in ferns, where the prismatic form of the spiroid is most frequently seen.

Poreous Vessels are tubes with bright spots upon their walls (fig. 4, h, i); they constitute the Continuous Bothrenchyma of Lindley. They are found in greatest abundance in the old wood of *Conifera*, in the same positions where spiral vessels are found, in the young wood, and also in the roots of plants.

Dotted Vessels constitute the tissue which has been called Glandular Woody Tissue, and to which Meyen applies peculiarly the term Prosenchyma. (Fig. 3; fig. 4, b.) The dotted vessel, like the dotted cell, has dark spots on the inside of its membranous walls; but in addition to the dot there is also a circle. This dot does not appear to be formed by the remains of a partly-absorbed fibre, or the crossing of the fibres, as in some of the forms of porous cells and vessels, but from the sinuous flexures of one or more fibres uniting together, and forming between them a little cavity or depression: this is attended with depression of the external membrane, which gives the appearance of the larger circle surrounding the depression. (Fig. 2; fig. 4, b.) These phenomena make their appearance very early in the tissues of Coniferous plants; but if buds and very young plants are examined, the sinuous spiral vessels, called by Link *Vasa Spiroidea Fibrosa*, may be easily seen.

For information on the functions of these tissues, see the articles CELLS; SAP; REPRODUCTION IN PLANTS AND ANIMALS.

(Mohl, *On the Vegetable Cell*, translated by Hofmeyr; Schleiden, *Principles of Scientific Botany*, translated by Lankester; Link, *Elementa Philosophiæ Botaniciæ*; Meyer, *Pflanzen Physiologie*; Unger, *Botanical Letters*, translated by Paul; Braun, *Rejuvenescence in Nature*, translated for the Ray Society.)

TITANIUM. This metal was first recognised by Mr. Gregor, in 1791, as a distinct substance. He detected it in a black sand found in the bed of a rivulet near Menaccan in Cornwall. In 1795 Klaproth discovered it in some other minerals, and he gave it the name it now

bears. The properties of titanium were not however satisfactorily determined until 1822, when Dr. Wollaston examined and described it as it occurred in its perfect metallic and crystallised state, in the slag of an iron furnace at Merthyr Tydfil in South Wales. The form of the crystals is the cube; their colour resembles that of bright copper; they are sufficiently hard to scratch rock-crystal, and their specific gravity is 5.3.

Titanium enters into a great many minerals, some of which are described under their names; the remainder will be described here.

Anastase, Octadrite, or Oisanite.—This is protoxide of titanium nearly pure. It occurs in attached and imbedded acute octohedral crystals. Primary form a square prism. Cleavage parallel to the terminal planes and to those of the octohedron. Fracture conchoidal, indistinct. Hardness: scratches phosphate of lime, and is scratched by quartz. By friction it becomes negatively electrical, and when heated gives out a reddish-yellow phosphorescent light. Colour various shades of brown, more or less dark, sometimes indigo-blue. Streak white. Lustre adamantine. Translucent, transparent. Specific gravity 3.826. It is found in Cornwall, in Dauphiny, at Bourg-d'Oisans, in Spain, Switzerland, and some other places. It consists almost entirely of oxide of titanium, probably the protoxide.

Rutile, or Titanite; Peroxide of Titanium, or Titanic Acid.—It occurs crystallised and in crystalline masses. Primary form a square prism. Cleavage parallel to the lateral planes. Crystals frequently geniculated. Fracture uneven. Hardness: scratches glass, and sometimes quartz. Colour red, reddish-brown, and occasionally yellowish. Streak very pale brown. Lustre adamantine. Translucent, transparent, opaque. Specific gravity 4.249 to 4.4. It occurs not unfrequently inclosed in quartz, in fine red filamentous crystals. Rutile is found in Perthshire, Bohemia, Switzerland, especially at St. Gothard, and in various other parts of Europe; and also in Brazil and North America. According to H. Rose, it consists of—oxygen, 33.95; titanium, 66.05. It is frequently more or less mixed with oxide of iron and of manganese, and sometimes with oxide of chromium.

The minerals which are next described are the titanates of iron: they vary greatly both in form and composition, some being crystallised and others granular; the latter are frequently termed titaniferous iron-sand.

Kibdelophan—Axotomous Iron.—It occurs in imbedded crystals. Primary form a rhomboid. Cleavage perpendicular to the axis, distinct. Fracture conchoidal. Hardness 5.0 to 5.5. Brittle. Colour dark iron-black. Streak black. Lustre imperfect metallic. Opaque. Specific gravity 4.661. It is found at Gastein in Salzburg, in Sweden, and Siberia. The following is an analysis of a specimen from Gastein, by Kobell:—

Titanic Acid	59.00
Protoxide of Iron	36.00
Peroxide of Iron	4.25
Protoxide of Manganese	1.65

—100.9

Ilmenite.—It occurs in imbedded crystals. Primary form a right rhombic prism. No cleavage observed. Fracture uneven to conchoidal, with a vitreous lustre. Hardness 5.0; scratches glass slightly. Colour black. Opaque. Specific gravity 5.43. It is found near Lake Ilmen in Siberia. The analysis by Mosander gives—

Titanic Acid	46.92
Protoxide of Iron	37.86
Peroxide of Iron	10.74
Protoxide of Manganese	2.73
Magnesia	1.14

—99.39

Crichtonite.—It occurs in attached crystals. Cleavage parallel to the axis. Fracture conchoidal, splendent. Hardness: scratches fluor-spar, but not glass. Brittle. Does not obey the magnet. Colour shining black. Streak black. Lustre imperfect metallic. Opaque. Specific gravity 4. It has not been completely analysed; but, according to Berzelius, it consists of titanic acid and oxide of iron.

Granular Titanate of Iron and Titaniferous Iron-Sand present the following varieties:—

Nigrin.—It occurs in flat rounded grains of about the size of a pea, with occasional indications of a crystalline form. Structure foliated. Very hard. Brittle. Colour grayish-black. Lustre metallic. Specific gravity 4.445. It is found in Transylvania. Its analysis by Klaproth gives—

Titanic Acid	84
Protoxide of Iron	14
Protoxide of Manganese	2

—100

Menaccanite occurs in small angular grains. Structure imperfectly lamellar. Fracture fine-grained, uneven. Hardness: yields to the knife. Colour grayish-black. Lustre glistening. Opaque. Specific gravity 4.427. It occurs in rivulets in the parish of St. Keverne, Cornwall; and has also been found in New South Wales. The picked grains, analysed by Dr. Colquhoun, gives—

Titanic Acid	57.187
Protoxide of Iron	39.730
Protoxide of Manganese	2.175

—99.142

Iserine occurs in very small flattish angular grains, which have a rough glimmering surface. Structure lamellar. Cross fracture conchoidal. Very hard. Slightly attracted by the magnet. Opaque. Lustre semi-metallic. Specific gravity about 4.5. It is found on the Riesengebirge, near the origin of the river Iser in Silesia; in Bohemia; in the river Don in Scotland, and that of the Morsey opposite Liverpool. By the analysis of H. Rose it consists of—

Titanic Acid	50.12
Protoxide of Iron	49.88

—100

It is probably a variety of Menaccanite.

Sphène—Spinthère—Silico-Titanate of Lime—occurs in attached and imbedded crystals, and massive. Primary form an oblique rhombic prism. Cleavage indistinct. Fracture even, slightly conchoidal. Hardness: scratches phosphate of lime, but is scratched by felspar. Colour various shades of gray, green, yellow, and brown. Streak white or grayish-white. Lustre adamantine, resinous. Transparent, translucent, opaque. Specific gravity 3.463 to 3.6. Sphène is found interspersed in primary rocks, as in granite and gneiss, and more particularly in syenite, in Norway, Germany, Switzerland, and also in America. The results of the analysis of sphène vary considerably; the following is by Klaproth:—

Titanic Acid	33
Silicic Acid	35
Lime	33

—101

Eschynite—Titanate of Zirconia and Cerium, &c.—occurs crystallised. Primary form a right rhombic prism. Cleavage difficult, and only parallel to the bases of the primary form. Fracture conchoidal. Hardness: scratches phosphate of lime, and is scratched by felspar. Colour black; streak grayish-black. Lustre resinous. Opaque. Specific gravity 5.14. It is found at Miask, in the Uralian Mountains Siberia. The analysis by Hartwall gives—

Titanic Acid	56.0
Zirconia	20.0
Oxide of Cerium	15.0
Lime	3.8
Oxide of Iron	2.3
Oxide of Zinc	0.5

—97.9

[BROOKITE; MOHSITE; GREENOVITE; PEROVSKITE; PYRRHITE; WARWICKITE; PYROCHLORE; ZIRCONIA; ENCELADITE; POLYMIGNITE.]

TITLARKS, the common name for the species of *Anthus*, a genus of Birds belonging to the family *Alaudineæ*. [ANTHUS.] The species are also called Pipits. The following are British species:—

Anthus trivialis, the Tree-Pipit; *A. pratensis*, the Meadow-Pipit; *A. obscurus*, the Rock-Pipit (*A. petrosus*, Flem., Jen.; *A. aquaticus*, Selby, Gould; *A. obscura*, Auct.); and *Anthus Ricardi*, Richard's Pipit.

Foot of Tree-Pipit. (Yarrell.)

Tree-Pipit (*Anthus trivialis*). (Gould.)

The Titlark of Pennant is the Meadow-Pipit of the above list; and Mr. Yarrell well observes that scarcely any two British birds have been

so frequently confounded together as the Tree- and the Meadow-Pipits; but when the two species are examined in hand obvious and constant distinctions appear; and there are, he adds, besides, differences in the habits of these birds, as well as in the localities they each frequent. "The Tree-Pipit is rather the larger bird of the two; the beak is stouter and stronger; the spots on the breast longer and fewer in number; the claw of the hind toe is not so long as the toe itself; the tertial feathers of the wings are rather longer in proportion to the primaries; the white on the outer tail-feather on each side is neither so pure in colour nor is it spread over so large a portion of the feather; and, as far as my own observation goes, it does not appear to be so numerous as a species as the Meadow-Pipit."

We give illustrations of these two common British species.

The Tree-Pipit is a migratory bird; but the Meadow-Pipit remains with us throughout the year, and is the smallest and most common species, its total length being 6 inches only.

Foot of Meadow-Pipit. (Yarrell.)

Meadow-Pipit (*Anthus pratensis*), male and female. (Gould.)

TITMOUSE. [PARIDÆ.]

TIT-WARBLERS, Mr. Swainson's name for a sub-genus of his sub-family *Paridae*, and considered by him as the second or typical division of the whole group.

Sylvicola minuta is an example of these birds. Its colour is blue-gray, beneath golden-yellow; back olive; wing-coverts tipped with white. It is a native of Brazil.

Gray-Backed Warbler (*Sylvicola minuta*). (Swainson.)

TOAD. [AMPHIBIA; BUFON.]

TOAD-FLAX. [LINARIA.]

TOBACCO. [NICOTIANA.]

TODDALLIA, a genus of Plants belonging to the natural order Rutaceæ

tribe *Xanthoxyleæ*, which is itself sometimes made into a distinct order. The name *Toddalia* is derived from Toddali, the Malabar name of one of the species. The genus is distinguished by having unisexual flowers, the calyx 5-toothed; petals 5; stamens 5, longer than the petals; stigma almost sessile, peltate; fruit fleshy, 5-furrowed, 5-celled, cells 1-seeded; seed kidney-shaped; embryo arched.

T. aculeata has prickly stems and branches, and extends to 30° N. lat., along the jungly base of the Himalayan Mountains. The bark and root of this species are said to be used as a cure for the remittent fever of such situations; and as many of the allied plants are possessed of bitter with aromatic properties, it is probable that this plant also may be useful for such purposes.

TODIRAMPHUS. [HALCYONIDÆ.]

TODUS. [MUSCIPIDÆ.]

TOES. [SKELETON.]

TOFIELDIA, a genus of Plants belonging to the natural order *Colchicaceæ*. It has a 6-parted perianth, the anthers bursting longitudinally; the 3 capsules, connected to above the middle, are 1-celled and many-seeded.

T. palustris is the only British species.

TOLU, BALSAM OF. [MYRSOPERMUM.]

TOMATO. [SOLANUM.]

TONGA or TONQUIN BEAN. [COUMAROUNA.]

TONGUE. The human tongue has a very complex structure, in correspondence with the variety of its offices as an organ both of sensation and of voluntary motion. The sensations which are perceived by means of the tongue are of two kinds, namely, that of taste and that of touch or tact; its motions are chiefly subservient to speech and to the prehension and swallowing of food. The sensitive apparatus of the tongue is contained in the membrane which covers it; its motor apparatus forms its interior.

The form and other external characters of the tongue may be easily observed by the aid of a mirror. Its surface is covered by a membrane continuous at the sides and lower part with that which lines the mouth and cheeks, and covered by a fine cuticle which is constantly kept moist by the saliva and by the secretion from the tongue itself. The membrane on the inferior surface of the tongue is thin, smooth, and transparent; at the middle line it forms a vertical fold which extends nearly to the tip of the tongue, and is named the *Frenum Lingue*. The membrane on the sides and upper part of the tongue is thicker and more vascular, and bears the *Papillæ*, the most sensitive parts, which are thickly set over its whole surface.

The *papillæ* of the tongue are of three different kinds:—1. The *Papillæ Vallatæ*, or *Magnæ*, are usually seven or nine in number, but sometimes are as many as twenty or as few as three. They are situated at the back part of the tongue, in two rows forming an angle, like the letter V, with its apex directed backwards. Each of them has the form of a truncated cone, and consists of a number of fine cylindrical processes closely held together. They are set in rather deep depressions of the membrane, so that they seem to be surrounded by fossæ which are bounded by elevated rings. 2. The *Fungiform* or *Lenticular Papillæ* are smaller, but much more numerous than the preceding, and are scattered at irregular distances from each other over the whole of the upper surface and sides of the tongue. They vary in form, some being hemispherical, some nearly cylindrical, and some having narrow stems which support larger summits, so as to have somewhat the shape of mushrooms. These also, like the preceding kind, are composed of numerous delicate filaments closely united. 3. The *Conical* and *Filiform Papillæ* cover all the remaining parts of the upper surface and sides of the tongue.

All these *papillæ* are very vascular, and receive filaments of the sensitive nerves of the tongue. Their structure is similar to that of the sensitive *papillæ* of the skin.

The interior of the tongue is composed entirely of muscles, and of the fat and cellular tissue which lie between their fibres. These muscles are named, after the parts to which they are attached, the *Ilio-Glossi*, *Stylo-Glossi*, *Genio-Hyo-Glossi*, and *Linguales*.

But besides these muscles, and variously intermingled with their fibres, the tongue contains numerous other irregular fasciculi, of which no description can be given. It is also variously influenced by the muscles which move the soft palate and its arches and the hyoid bone.

For its movements and its double sensibility the tongue is supplied with three different pairs of nerves:—1, The *Hypoglossal*, or *Lingual*, or ninth pair of nerves [BRAIN; NERVOUS SYSTEM], are distributed almost exclusively in the muscles of the tongue: they are its motor nerves; and when they are paralysed, compressed, or divided, the tongue is rendered immovable, but its sensations are unimpaired. 2, The *Lingual* (or, as they are sometimes called, the *gustatory*) branches of the fifth pair of nerves are those on which the sensibility of the tongue to all common impressions of touch, heat, cold, &c. depends. They are distributed most abundantly in the *papillæ* at and near the tip of the tongue, and they endow it with a sensibility more acute than that possessed by any part of the skin. 3, The *Gustatory*, *Glossopharyngeal*, or eighth pair of nerves, of which a considerable part is distributed in the tongue, are probably those on which the peculiar sense of taste depends.

The quality by which substances are capable of exciting the sensa-

tion of taste is altogether unknown, nor has even a probable hypothesis been formed. The best examples of merely acid substances are the various alkaline and metallic salts, and the inodorous hitters. By experiments with these the sense of taste is found to be enbject to many of the same rules as the other senses, and to be especially analogous to that of smell. [SMELL.] A certain force of application of the stimulus heightens the perception of it. Men instinctively press the tongue against the roof of the mouth and 'emack' it, to obtain a clear sense of taste, as they inspire quickly in the act of smelling. Contrast of tastes also commonly makes that which is last perceived more obvious, as the eye passing from one colour to another, or the nose from one odour to another, perceives each in succession the more acutely; and there are subjective sensations of taste, as there are of sight and hearing. Such are those produced by the contact of two different metals with each other and with the tongue, and those which are perceived in various diseases; but the circumstances on which they depend are as yet unknown.

TONQUIN or TONGA BEAN. [COUMAROUNA.]

TONSILS. The Tonsils are two complex glands, one of which lies on each side of the fauces, between the arches of the soft palate. They are of an elongated oval form, and each is composed of a number of smaller glands aggregated together in one mass, and usually opening by several orifices on the surface of the mucous membrane. They form a continuous layer with a great number of similar glands, which are contained in the substance of the palate, in the root of the tongue, and in the space between the tongue and the epiglottis; and with these the tonsils form a complete ring of glandular tissue around the aperture leading from the mouth to the pharynx. The nature of the fluid secreted by them is not certainly known. It bears a general resemblance to saliva, and probably serves chiefly to lubricate the food for its passage from the mouth to the stomach.

TOON-WOOD. [CEDRELA.]

TOPAZ, a Mineral. It occurs massive, in imbedded and rounded crystals. Primary form a right rhombic prism. Cleavage easy, parallel to the base of the primary form, more difficult in the direction of its lateral faces. Structure lamellar at right angles to the axis of the prism. Fracture uneven, rightly conchoidal. Hardness: scratches quartz. Electricity: positive by friction; those crystals which possess different faces of crystallization at opposite ends acquire different kinds of electricity at the two extremities when heated. Colour white, yellow, bluish, and greenish. Lustre vitreous, transparent, translucent. Specific gravity 3.499. Fragments exposed to heat emit a blue, green, or yellowish phosphoric light. By the blow-pipe on charcoal it does not fuse, but with borax it melts into a transparent glass. Topazes occur generally in primitive rocks, and in many parts of the world, as Cornwall, Scotland, Saxony, Siberia, Brazil, &c.

The following analyses have been given of this mineral: (1) Saxon topaz by Klaproth; (2) Brazilian topaz by Klaproth; (3) Saxon topaz by Berzelius; (4) Brazilian topaz by Berzelius:—

	(1)	(2)	(3)	(4)
Silica	35	44.5	34.24	34.01
Alumina	59	47.5	57.45	58.38
Fluoric Acid	5	7.0	7.75	7.79
Oxide of Iron	—	0.5	—	—
	99	99.5	99.44	100.18

The ancient *Topazion* was found on an island in the Red Sea, which was often surrounded with fog, and therefore difficult to find. It was hence named from 'topazo', to seek. This name, like most of the mineralogical terms of the ancients, was applied to several distinct species. Pliny describes a statue of Arsinoë, wife of Ptolemy Philadelphus, four cubits high, which was made of topazion, or topaz, but evidently not the topaz of the present day, nor chrysolite, which has been supposed to be the ancient topaz. It has been conjectured that it was a jasper or agate; others have imagined it to be prase, or chryoprase.

Topaz is employed in jewellery, and for this purpose its colour is often altered by heat. The variety from Brazil assumes a pink or red hue, so nearly resembling the Balas ruby, that it can only be distinguished by the facility with which it becomes electric by friction. The finest crystals for the lapidary are brought from Minas Novas, in Brazil. From their peculiar limpidity, topaz-pebbles are sometimes denominated Gouttes d'Eau. When cut with facets and set in rings, they are readily mistaken, if viewed by daylight, for diamonds. The coarse varieties of topaz may be employed as a substitute for emery in grinding and polishing hard substances.

Topaz is cut on a leaden wheel, and is polished on a copper wheel with rotten stone. It is usually cut in the form of the brilliant or table, and is set either with gold foil or 'à jour.' The white and rose-red are most esteemed.

(Dana, *Manual of Mineralogy*.)

TOPAZOLITE. [GARNET.]

TORDYLUM (*Τορδύλιον* of Dioscorides), a genus of Plants belonging to the natural order *Umbelliferae*. The calyx consists of 5 awl-shaped teeth; the petals orbiculate, with an inflexed lobe, the outer ones radiant. The fruit has a thick wrinkled margin; the pericarps with very slender ribs; the 3 dorsal ribs at equal distances, the

2 lateral ones contiguous to the thickened margin or covered by it. The species are herbs, with pinnate leaves and ovate leaflets deeply toothed. The flowers are white.

T. maximum, Great Hart-Wort, has a scabrous or hispid stem, pinnate leaves, and lanceolate leaflets deeply notched and clothed with fine bristly hairs. It is a native of England.

T. officinale, Official Hart-Wort, has a branched furrowed stem, clothed with soft deflexed hairs; the leaves are pinnate, rough, and hairy; the leaflets ovate, cut, and crenate. The 2 outer petals are radiant, each with 2 very unequal lobes, which are sometimes reddish. It is the *Σέσελι* of Hippocrates ('*Vict. Acut.*' 387) and of Theophrastus ('*Hist. Plant.*' 9, 18); the *Seell* of Pliny (25, 8).

TORENIA, a small genus of Plants of the natural family of *Scrophulariaceae*, found in India, the tropical parts of Australia, and in South America. *T. Asiatica*, a species found in almost every part of India, is described by Rheede as having the juice of its leaves employed as a cure for gonorrhoea on the coast of Malabar.

TORILIS, a genus of Plants belonging to the natural order *Umbelliferae*. The calyx has 5 teeth; the petals are obovate, emarginate, the outer ones radiant and bifid; the fruit slightly and laterally compressed; the carpel with bristly primary ridges, the secondary hidden by the numerous prickles which occupy the interstices; the flowers white, those in the disc of the umbellules male and sterile.

T. anthriscus has bipinnate leaves, the leaflets ovate, lanceolate, inciso-serrate; the umbels on long peduncles, the leaves of the involucre awl-shaped, the fruit covered with histles; the flowers are small, reddish or white. It is a native of Europe and the Caucasus, and is plentiful in Britain.

T. infesta has an erect much-branched stem, the leaves bipinnate, the leaflets deeply cut, ovate, lanceolate. The fruit is densely prickly, the flowers small and reddish. It is found on fields and waste places in Europe and Great Britain.

T. nodosa has nearly sessile dense umbels, the outer carpels with hooked bristles, the inner often covered with dense whitish shining granulations; the lower leaves are bipinnate, the upper ones pinnate; the leaflets deeply, narrowly, and uniformly pinnate. It is a native of Europe and the Levant, and is plentiful in Britain.

TORMENTILLA. [POTENTILLA.]

TORPEDINIDÆ, the Torpedoes, a family of Fishes belonging to the order *Plagiostomi*, and the sub-order *Raiine*. [RAIINÆ.]

Torpedo, the principal genus, was founded by Duméril upon the *Raia Torpedo* of Linnæus, and some other species, distinguished by their having the tail short and moderately thick, and the disc of the body nearly circular, the anterior margin being formed by two produced portions from the head, which, inclining sideways, join the pectorals: the space between the head, the pectoral fins, and the branchiæ is occupied by small vertical hexagonal tubes, which are filled with mucous matter, and largely provided with nerves from the eighth pair. The situation of these honeycomb-like cells, which constitute the electrical apparatus, is indicated on the upper surface by a slight convexity on each side of the head. [ELECTRICITY OF ORGANIC BEINGS.]

Cuvier and Risso consider that several species have been confounded under a common name, and the latter of these authors has characterised four species of *Torpedo* in his '*Histoire Naturelle de l'Europe Méridionale*.' They are—

1. *Torpedo Narke*, which he describes as being yellowish-red above, and having five ocellated spots.

2. *Torpedo unimaculata*. This species has the body above fulvous, spotted with whitish spots, and one oblong ocellated spot in the middle of the back. The tail is more elongated and slender. It is said to have the electrical apparatus scarcely visible, and to give but very slight shocks.

3. *Torpedo marmorata*. Body flesh-coloured, and having brown spots and sinuous markings, producing a marbled appearance: tail thick, above rounded.

4. *Torpedo Galvani*. Body fulvous, immaculate, but margined with black.

Fleming refers the British *Torpedo* to the third of these species *Torpedo marmorata*.

TORPEDO. [TORPEDINIDÆ.]

TORS. By the natural weathering of rocks exposed to atmospheric vicissitudes, the perishable parts are removed and the more resisting portions remain. In rocks which manifest peculiar arrangements of joints or natural divisions, the blocks and masses defined by their intersections often appear in cubical, subcolumnar, and other characteristic shapes. To masses more or less characteristic in figure, left by the decay of surrounding parts in prominent situations, the name of 'Tor' is applied in the granitic tracts of Devon and Cornwall.

TORSK. [BROSIMUS.]

TORTOISES. [CHELONIA.]

TORTRIX, a genus of Serpents. [BOIDÆ; OPHIDIA.]

TORULA. [MOULDINESS.]

TOTANUS. [SCOLOPACIDÆ.]

TOTIPALMES, Cuvier's name for a group of Birds whose hind toe is united together with the others in a continuous membrane. The Pelicans, the Cormorants, the Frigate Birds, the Boobies, the Anhingas, and the Tropic Birds belong to this group.

TOUCANS. [RAMPHASTIDÆ.]

TOUCH. The sense of touch belongs to the outward integument of the body—the skin, and is shared, in a minor and modified degree, by parts of the mucous membranes, which, at the various orifices of the body, are continuous prolongations of the same structure. By it we have the faculty of determining our immediate relations to material objects, in regard of contact, temperature, and electrical excitement.

The nervous influence, or endowment, on which this sense depends, appears in no essential particular to be distinguished from that which gives common sensibility to the various deeper organs of the body. The nerves which convey the specific impressions of touch, are associated at their origin, or in their course, with others not reaching to the surface of the body, under the common name of sensitive; so that if we trace such a one from the centre outwards, we find it (previously to its termination in the skin, where it ministers to the special sense of touch) supplying parts which have merely that common feeling, or sensibility to pain, necessary to their own preservation.

In order to that high development of the sense of touch, which we notice in the human hand, or in the proboscis of the elephant, certain anatomical peculiarities are required:—

1. An exposure of the largest possible number of points, each endowed with sensibility, and capable of being recognised in the sensorium, as distinct and individual. Such a structure is eminently illustrated in the papillary surface of the skin; which presents a vast number of minute evolutions, or papillæ, every one furnished with its own fibrillary nervous loop, and a minute insculcation of blood-vessels. It is certain that each terminal loop is represented by a definite point in the brain, that no two nervous fibrillæ become blended or confused, and hence that each papilla may originate a single and particular sensation. Perhaps the strongest familiar evidence that can be adduced for this fact, is furnished in the tingling sensation (called 'pins and needles') which we produce in numbing the nerve of a part by pressure; the impression here made on the trunk of a nerve being referred, according to a well-known physiological law, to its cutaneous extremities; so that when, for example, we strike the funny-bone, or otherwise press the ulnar nerve which lies there, the peculiar tingling is felt in the skin, at the tips of the last two fingers: if this sensation be analysed, we find it to consist in a pricking of innumerable minute points, as though there were falling on the part a quick dense shower of the finest needles: the minute points, so made sensible to us, are single papillæ of the skin. This instance of subjective sensation is probably the only mode in which the sensitive faculty of the skin can be made known to us; for obvious reasons prove it impossible to apply to the organs of touch the same precise admeasurements as we may use in ascertaining the power of the eye or of the ear. It appears however that the tactile power of the skin varies for different parts in a very much greater degree than can be accounted for by differences in nervous supply. Professor Weber has measured the power of distinguishing distances in different parts of the skin, with the view of affording means to compare their relative degrees of endowment. He conducted his experiments by touching the surface with the points of a pair of compasses (blunted with pieces of cork), and observing how close their arms might be brought together, and still be felt each distinctly. He found that the point of the tongue could distinguish them, as two impressions, when distant only half a line from each other; and that in the middle of the back a separation of thirty lines was necessary to the distinction. Thus, while the tactile endowment of a part is in proportion to the minuteness and density of its papillation, it is evident that the applicability and development of this property will depend on habit and attention and practice, by which we acquire the power of appreciating minute differences of impression.

2. In addition to the anatomical arrangement just described, the sense of touch requires for its perception that a muscular apparatus should be connected with the sentient surface, by means of which this may adapt itself to the superficies of bodies, in order to explore their outline, span their dimensions, or probe their texture. And we find accordingly in those organs which are most tactile,—the hand, the tongue, the lips of the human subject, the snout, proboscis, or tentacles of lower animals,—that complicated muscular motions belong to the part, and render it a more available instrument of exploration. The importance of this addition becomes manifest, if we apply a foreign object to any plane surface of the body (to the front of the fore arm, for instance), and hold it there without pressure or motion. The only sensation so conveyed is one of indefinite contact: without pressure we know not its consistence; without successive and exploring movement we cannot ascertain its outline or level.

(Kirke, *Handbook of Physiology*; Valentin, *Textbook of Physiology*.)

TOUCH-ME-NOT. [IMPATIENS.]

TOUCHSTONE. [FLINTY SLATE.]

TOURACOS. [MUSOPHAGIDÆ.]

TOURMALINE (*Schorl*), a Mineral occurring crystallised. Primary form a rhomboid; secondary forms, prisms with from 3 to 12 sides, terminated by very irregular summits. Cleavage parallel to the faces of the primary form. Fracture uneven, conchoidal. Hardness: scratches glass easily. Electricity: according to Haüy the transparent varieties when heated become electric; the termination of the prism which presents the greater number of faces becoming positive, while the other end becomes negative. Colour white, brown, blue, yellow,

green, red, and black. The blue variety is called *Indicolite*, and the red *Rubellite*. *Schorl* is a name formerly given to black tourmaline. Lustre vitreous. Transparent, translucent, opaque. Specific gravity 3·069 to 3·076. Before the blow-pipe all the varieties fuse readily with borax, producing at first slight effervescence.

Tourmaline occurs most commonly in primary rocks, especially in granite, gneiss, and mica slate. The red variety, or rubellite, is found in Siberia; the blue, or indicolite, at Uto; the green in Brazil; the black in Devonshire and many other places. The composition of tourmaline is extremely various. That of the red appears, from the analysis of Vauquelin, to be the simplest, consisting of—

Silica	42
Alumina	40
Soda	10
Oxide of Manganese	7
	—99

Some varieties contain also potash, lithia, lime, magnesia, oxide of iron, and boracic acid. The proportions of these constituents are extremely variable, and no one variety contains all the enumerated substances. The black tourmaline from Devonshire yields nearly 19 per cent. of oxide of iron, and that of Eibenstock nearly 24 per cent. of the same oxide.

The word Tourmaline is a corruption of the name in Ceylon, whence it was first brought to Europe. *Lyncurium* is supposed to be the ancient name for common tourmaline; and the red variety was probably called *Hyacinth*.

The red tourmalines, when transparent and free from cracks, are of great value, and afford gems of remarkable beauty. They have all the richness of colour and lustre belonging to the ruby, though measuring an inch across. A Siberian specimen of this variety, now in the British Museum, is valued at 500*l*. The yellow tourmaline, from Ceylon, is but little inferior to the real Topaz, and is often sold for that gem. The green specimens, when clear and fine, are also valuable for gems.

Tourmaline, on account of its property of polarising light, is used largely in the manufacture of polarising instruments.

(Dana, *Manual of Mineralogy*.)

TOURNEFORTIA, a genus of Plants belonging to the natural order *Boraginaceæ*, so named by Linneus in honour of Joseph Pittou de Tournefort. It is characterised by having a salver-shaped or rotate corolla, of which the throat is naked; the stamens included within the tube of the corolla; the stigma is peltate, and the fruit consists of a berry which contains 4 1-seeded nuts. The species are about 50 in number, forming small shrubs or herbs, diffused through the bot parts of the world, as the West Indies, South America, Indian islands, and India.

TOXICODENDRON. [RHUS.]

TOXODON (τόξον, a bow; ὄδων, a tooth—from the curvature of the teeth), Professor Owen's name for an extinct genus founded on *Toxodon Platensis*.

Mr. Darwin, during his sojourn in Banda Oriental, having heard of some giants' bones at a farm-house on the Sarandía, a small stream entering the Rio Negro, rode there and purchased, for the value of eighteen-pence, the cranium now in the Museum of the Royal College of Surgeons in London, and the subject of Professor Owen's description. The people at the farm-house told Mr. Darwin, that the remains were exposed by a flood having washed down part of a bank of earth. When found the head was quite perfect; but the boys knocked the teeth out with stones, and then set up the head as a mark to throw at. Mr. Darwin found a perfect tooth, which exactly fits one of the sockets in this skull, embedded by itself on the banks of the Rio Torero, at the distance of about 180 miles from the farm-house. Near the *Toxodon* Mr. Darwin found what he terms the fragments of the head of an animal rather larger than the Horse, and which he describes as having some points of resemblance with the *Toxodon* and others, perhaps with the *Edentata*. These fragments, now also in the museum of the College, Professor Owen has ascertained to belong to the lower jaw of the *Toxodon*. Mr. Darwin observes that the remains appeared so fresh as to render it difficult to believe that they had lain buried for ages underground. The bone contained so much animal matter, that when heated in the flame of a spirit-lamp it not only exhaled a very strong animal odour, but likewise burned with a slight flame. ('*Journal*.) The place where the remains were found is about 120 miles N.W. from Monte Video, and the cranium was embedded in a whitish argillaceous earth forming the banks of the Sarandía.

The first notice of this discovery appears in the '*Proceedings of the Geological Society of London*,' in a paper by Professor Owen, from which we take the following brief account:—

The cranium measures 2 feet 4 inches in length, and 1 foot 4 inches in extreme breadth. The form of the skull is elongated, depressed, and chiefly remarkable for the strength and wide expanse of the zygomatic arches, and the aspect of the occipital foramen and occipital region of the skull, which slopes from below upwards and forwards. The maxillary portion of the skull is compressed laterally, narrow, and with large intermaxillary bones slightly dilated at their extremity.

The teeth consist of molars and incisors. The latter are four in number in the upper jaw, the two middle ones very small, the two

external ones very large, curved, and with their sockets extending backwards in an arched direction through the intermaxillary bones to the maxillary, and terminating, without diminishing in size, immediately anterior to the grinding teeth, where the large persistent pulps of these incisors were lodged. In form and relative size these teeth must have resembled the *dentis scalprarii* of the Rodents.

The molar teeth no less present a close approximation in their form and structure to the molar teeth of the Herbivorous Rodents. They are seven in number on each side of the upper jaw, and, from the form of the sockets, appear to have corresponded with each other in structure.

"After summing up the different affinities, or indications of affinity, which are deducible from this most curious and interesting fossil mammal, we are led to the conclusion, assuming it to have had extremities cased in hoofs, that it is referrible to the order *Pachydermata*; but the structure, form, and kind of teeth in the upper jaw prove indisputably that the gigantic *Toxodon* was intimately related to the Rodent order. From the characters of this order, as afforded by the existing species, the *Toxodon* however differs in the relative position of the supernumerary incisors, and in the number and direction of the curvature of the molars. If moreover the lower jaw, next to be described, belong, as I believe, to the *Toxodon*, the dental character of the genus will be—

"Incisores, $\frac{4}{6}$; Pro Laniaris Diastema; Molares, $\frac{7-7}{7-7}$."

"The *Toxodon* again deviates from the true *Rodentia*, and resembles the Wombat [*MARSUPIATA*] and the *Pachyderms* in the transverse direction of the articular cavity of the lower jaw. It deviates from the *Rodentia*, and resembles the *Pachydermata* in the relative position of the glenoid cavities and zygomatic arches, and in many minor details already alluded to.

Skull of *Toxodon Platensis*, profile.

Top view of the Skull of *Toxodon Platensis*.

Skull of *Toxodon Platensis*, seen from behind.

"The affinity above alluded to is too obvious to have escaped popular notice, and the Capybara, from its aquatic habits, has obtained the name of Water-Hog. It is highly interesting to find that the continent to which this existing aberrant form of Rodent is

peculiar should be found to contain the remains of an extinct genus characterised by a dentition which closely resembles the Rodent type, but manifesting it on a gigantic scale, and tending to complete the chain of affinities which links the *Pachydermatous* with the Rodent and Cetaceous orders."

Penultimate molar tooth (upper jaw) of *Toxodon Platensis*.

Incisor tooth of lower jaw of a *Toxodon*.

a, grinding surface of penultimate upper molar tooth of *Toxodon Platensis*;
b, grinding surface of a corresponding molar tooth of the lower jaw.

Fragment of anterior part of lower jaw of a *Toxodon*, with teeth in situ.
(All from Owen.)

TOXOSTOMA. [MERULIDÆ]
TOXOTES. [ARCHER-FISH.]

TRACHEARIA, a subdivision of the great class *Arachnida*. It includes those forms of this class which carry on their respiration by means of ramifying tracheal tubes. They have two or four eyes. This division includes the various forms of Mites, Ticks, Shepherd-Spiders, and Sea-Spiders. The following is a synopsis of the families of this sub-class from the 'Mammal of Natural History,' by Messrs. Adams, Baikie, and Barron:—

Order I.—*Monomerosomata*.

Body without division, the head, trunk, and abdomen being united into a single mass; abdomen not annulated.

Sub-Order I.—*Eirantia*.

Mouth with distinct mandibles; palpi always present; animals free.

Family 1. *Acaridae*.—This includes the True Mites. [ACARIDÆ.]

Family 2. *Trombidæ*, Garden-Mites.—Palpi jointed, with a moveable appendage below the tip; feet formed for walking; eyes latero-anterior; chelicerae ending in a moveable claw.

Trombidium holosericeum is of a blood-red colour, and is very common in gardens during the spring.

Family 3. *Gamasidæ*, Spider-Mites.—Palpi filiform, incurved, short, free; mouth with two didactyle chelicerae; body depressed; skin soft or scaly; legs formed for walking; tarsi unguiculate. The Red Spider of our bot-houses belong to this family.

Family 4. *Orbitidæ*, Wood-Mites.—Palpi fusiform, hid under the head, without books; mouth with didactyle chelicerae; eyes not distinct; body hairy or scaly, produced and rostrate in front; legs formed for walking.

Sub-Order II.—*Suctoria*.

Mouth in form of a sucker, with or without palpi; no apparent mandibles; animal attached.

Family 5. *Ixodidæ*, True Ticks. [IXODES.]

Family 6. *Bdellidæ*, Plant-Ticks.—Palpi antenniform; mandibles unguiculate or cheliform; eyes distinct; suckers in form of an elongated beak; body with a caselet; legs formed for walking.

Family 7. *Hydrachnidæ*, Water-Ticks.—Palpi with the last joint armed with points, the third and fourth joints larger than the others; body simple, oval, or rounded; eyes supero-anterior; legs ciliated, formed for swimming; parasitic in the young state; aquatic.

The species are found in fresh-waters. *Hydrachna* has the mouth composed of plates forming a projecting sucker.

Family 8. *Leptidæ*, Harvest-Ticks.—Palpi short; suckers protracted; body depressed, coriaceous, ovately rotund; legs six, two being undeveloped.

Leptus autumnalis is very common in autumn upon grass and other herbage. They crawl upon the human body and insinuate themselves into the skin, producing great irritation. They are called Harvest-Bugs.

Order II. *Adelarthrosomata*.

Body divided into three or four distinct segments; abdomen distinct, annulated; mouth with conspicuous didactyle pincers or chelicerae.

Family 1. *Solpugidæ*, False Scorpions.—Mandibles in the form of large compressed claws, with a moveable finger; palpi large, in the form of feet, or of cheliferous arms; body oblong, soft; abdomen hairy.

Family 2. *Cheliferidæ*, Book-Scorpions.—Mandibles short; didactyle at the end; palpi very large, awn-like, with a pincer at the end; body ovate, depressed, narrowed in front; legs of equal size, short, ending in two hooks. *Chelifer cancrivorus* is found in herbariums, old books, &c., where it feeds upon the minute insects which frequent such situations.

Family 3. *Phalangidæ*, Shepherd-Spiders.—Mandibles very conspicuous, composed of two or three pieces, free, ending in a didactyle pincer; palpi filiform, ending in a hook; body short, rounded; abdomen segmented; legs elongated. This family comprises the well-known forms called Harvest-Men.

Sub-Class III. *Aprobranchiata*.

This sub-class includes the genera *Nymphon* and *Pycnogonum*, which are the types of two families, *Nymphonidæ*, the Sea-Spiders, and *Pycnogonidæ*, Parasitic Sea-Spiders. These are often referred to the class *Crustacea*. [SIPHONOSTOMATA.]

TRACHELIASITES. [LERNEADÆ.]

TRACHELIDES. [HETEROMERÆ.]

TRACHELIOPTERUS. [SILURIDÆ.]

TRACHELIPODA. [MALACOLOGÆ.]

TRACHENCHYMA. [TISSES, VEGETABLE.]

TRACHIURUS. [TENUIDÆ.]

TRACHYCEPHALUS. [IGUANIDÆ.]

TRACHYCYCLUS. [IGUANIDÆ.]

TRACHYPHONUS. [PICIDÆ.]

TRACHYPTERUS, a genus of Fishes belonging to the riband-shaped forms of *Acanthopterygii*. The body is elongated and compressed; dorsal fin extending the whole length of the back, a few of the anterior rays sometimes elongated; ventral fins fragile, if not worn or broken, rather long; no anal fin; caudal fin rays rising almost vertically from the horizontal line of the vertebral column; a row of small spines along the lateral line.

T. Bogmarus, the Vaagmaer, or Deal Fish, is described by Dr. Fleming in the 'Magazine of Natural History.' He was the first British naturalist who has made known its occurrence in Scotland. The species found in the north of Europe differ from those of the Mediterranean. One specimen only has been recently caught alive at Sanda in Orkney. It is thus described:—Length three feet; body excessively compressed, particularly towards the back, where it does not exceed a table-knife in thickness; breadth nearly five inches, tapering to the tail; colour silvery, with minute scales, the dorsal fin of an orange colour, occupying the whole ridge from the head to the tail, with the rays of unequal size; head four inches and a half long, compressed like the body, with a groove on the top; eyes one inch and a quarter in diameter; both jaws armed with small teeth. Various specimens, probably to the number of twelve or more, appear to have been obtained on the island of Sanda between 1817 and 1829. The Vaagmaer is rare in Iceland. It differs from the two species found in the Mediterranean, *T. falc* and *T. iris*, and also from *T. leiopterus*.

TRACHYTE. [ROCKS.]

TRACHYTELLA, a genus of Plants belonging to the natural order *Dillenaceæ*, so named from *τραχυτης*, 'roughness,' because the leaves are remarkable for their asperity. The genus belongs to the tribe *Delimaceæ*, of the above family, by having the sepals and petals from 4 to 5, numerous stamens, and 1 or 2 baccate many-seeded carpels. The known species are only two in number, natives of China and Cochinchina, climbing in habit, with racemes of white flowers. The leaves of *T. Actea* have so very rough a surface that they are employed in Canton for polishing both wood and metal.

TRADESCANTIA, a genus of Plants belonging to the natural order *Commelinaceæ*, which was so named in honour of the English botanist John Tradescant, who was gardener to Charles I. The species are natives of America and India. Many of them, being of a highly ornamental nature, are cultivated in flower-gardens; a few are used medicinally in the countries where they are indigenous. Thus *T. axillaris*, according to Rhædo, is used in India as an application to the abdomen in cases of tympanites; and Martius describes the stem and leaves of *T. diurctica* as being employed in Brazil as emollient applications in rheumatic pains, intestinal derangements, and in retention of urine; while in North America *T. virginica* is employed in cases of bites of venomous spiders, as well as some other species, whence it has obtained the name of Spider-Wort, but it is doubtful whether they possess any other than simple emollient properties. The hairs of the stamens of this plant exhibit a circulation, in the cells of which they are composed.

TRAGACANTH. [ASTRAGALUS.]

TRAGELAPHUS. [ANTILOPEÆ.]

TRAGIA, a genus of Plants belonging to the natural order *Euphorbiaceæ*, named after Tragus, a German botanist, whose real name was Bock. The species are found in India and in America, are climbing in habit, and some are remarkable for stinging as violently as nettles. *T. cannabina* is so named from its leaves resembling those of the *Cannabis*, or Hemp, and of which the roots given in infusion are considered diaphoretic and alterative. *T. involucrata* is a small plant without taste or smell, but the native physicians of India consider it calculated to strengthen the system in cachectic states of the constitution and in chronic cases of syphilis. *T. volubilis*, which is a stinging climber, and has a very acrid juice, is employed in conjunction with common salt for the destruction of some kinds of ulcers.

TRAGOPAN. [PIASIANIDÆ.]

TRAGOPO'GON (from *τράγος*, a 'goat,' and *πῶγων*, 'beard'), a genus of Plants belonging to the natural order *Cichoraceæ*, which is usually considered only a tribe of the great order of *Compositæ*. The genus *Tragopogon*, or Goat's Beard, is so named from the long silky beard or pappus of the seeds. The genus is distinguished by having a simple involucre of many leaves. Receptacle naked. Pappus stalked, plumose. Achenia longitudinally striated. The species are found in the temperate parts of Europe and of Asia. One, *T. gracilis*, is found in the Himalaya Mountains, of which the leaves are eaten by the natives as lettuce in Europe, but without being blanched. The best-known species however is *T. porrifolius*, or Salsify, which is occasionally cultivated in this country, but frequently in France and Germany. The English *T. pratensis* may be cultivated for the same purpose. The roots of Salsify are the parts esteemed; they are long and tapering, their flavour mild and sweetish, and are boiled or stewed like carrots. The stalks of year-old plants are sometimes cut in the spring, and, when similarly dressed, taste like asparagus.

TRAGOPS. [ANTILOPEÆ.]

TRAGULUS. [MOSCHIDÆ.]

TRANSITION ROCKS. When the general terms Primitive and Secondary were much in use among geologists, certain assemblages of rocks, which were of intermediate position, and seemed to unite the mineral aspect of the Primitive with the organic enrichments of the Secondary, were for these reasons called Transition Geblirge, *Roche de Transition*, and Transition Rocks. These terms are not much used at the present day. [GEOLOGY.]

TRAP. This geological term, one of the most general use and comprehensive signification, seems to have been originally employed by Bergman and the German and Swedish miners, in the sense of the word 'trappa,' Swedish, or 'treppe,' German, meaning stairs, and the

aspect of the rocks now called Trap, in successive terraces on hill sides, is such as often to justify the use of the word. In modern works on topographical geology a very great proportion of the ancient rocks of fusion are familiarly called Trap, not because they have any certain mineral composition, but because, whether granitic, sienitic, porphyritic, or hornblende, they appear under particular relations of position or geological age. In this sense the term is purely geological, and we have as distinctive designations Eruptive Trap, Contemporaneous Trap, Overlying Trap, Interposed Trap, &c. By other writers the term is restricted so as to leave out such massive and generally deep-seated rocks as granite, or even contracted to the hornblende and feldspatho-hornblende rocks, which appear as dykes, interposed beds, and overlying masses. It thus appears to be a collective term more convenient than precise. In a geological sense it may be replaced by descriptive words, such as Irruptive, Interposed, Overlying, &c., and in a mineralogical sense it is advantageously changed for Basalt, Greenstone, Felsparite, Sienite, Serpentine, Diabase Rock, &c.

TRAPA, a genus of Plants belonging to the natural order *Onagraceae*. The fruit of *Trapa* is furnished with spines, and the species are commonly called Water-Caltraps, from the plants floating on the surface of lakes, and on that of slow-running waters. They are found in the temperate parts of Europe and of Siberia, in Cashmere, India, Cochinchina, and China. The genus is characterised by having a 4-parted adherent calyx; petals and stamens 4; ovary 2-celled, with solitary pendulous ovules. The fruit is hard, indehiscent, 1-celled and 1-seeded. The seed is large and exalbuminous; the two cotyledons very unequal. The floating habit and clustered leaves easily distinguish these plants. The leaves under water are cut into capillary segments, and the petioles are tumid in the middle.

T. natans, the European species, is remarkable for its fruit with 4 spines, being of a blackish colour and large size, and its seed, which nearly fills it, being farinaceous, and good to eat, whether raw, roasted, or in soups, and is somewhat like a chestnut in taste. It was known to the Romans by the name *Tribulus*. Pliny says (lib. xxi., c. 53), "About the rivers Nilus and Strymon the inhabitants gather it for their meat."

T. bispinosa, Roxb. ('Corom. Pl.' ii. 234), has the nut with two opposite, straight, barbed, spinous horns, noticed by Sir W. Jones under the Sanscrit name of *Sringata*: it is commonly known all over India by the name *Singara*, both names having reference to its horned appearance. It is also found in the Lako of Cashmere. In India the nuts are sold in all the bazaars, as their farinaceous kernels are much esteemed by the Hindoos. A species called by the same name, *Singhara*, forms a considerable portion of the food of the inhabitants of Cashmere.

T. bicornis is distinguished from the last by its two horns being recurved and very obtuse. It is carefully cultivated in lakes, ponds, and other receptacles of water.

TRAPELUS, Cuvier's name for a genus of Lizards which have the form and teeth of the *Agama*, but their scales are small and without spines. They have no pores on the thighs.

Trapelus Egyptianus (Agama mutabilis, Merrem.).

T. Egyptianus is a small reptile, which sometimes puffs out its body, whence the name of *orbicularis*, Daudin. It is also remarkable for its changes of colour, hence it is called by the French *Le Changeant d'Egypte*.

TRASS. A deposit of volcanic ashes and scorice thrown out from the Eifel volcanoes, and accumulated in valleys and old lakes under the influence of water, is thus designated. It is equivalent, or nearly so, to the *Puzzolana* of the Neapolitans. (Lyell's 'Principles of Geology'.)

TRAVELLER'S JOY. [CLEMATIS.]

TRAVERTIN, the Italian term for Concretionary Limestone, produced from springs holding carbonate of lime in solution.

TREACLE-MUSTARD. [ERYSIMUM.]

TREE, COTTON. [GOSYPIUM; BOMBAX.]

TREE-FERN. [CYATHEA.]

TREE-FROGS. [AMPHIBIA.]

TREE-MALLOW. [LAVATERA.]

TREES. [EXOGENS; AGE OF TREES.]

TREFOIL. [TRIFOLIUM.]

TREFOIL, BIRD'S-FOOT. [LOTUS.]

TREMENDACEÆ, *Poreworts*, a natural order of Exogenous Plants, consisting of slender shrubs very much resembling heaths, usually covered with glandular hairs. The leaves are without stipules, either alternate or whorled, entire or toothed. The flowers are often large and handsome, seated on solitary axillary pedicels. The calyx has 4 or 5 sepals with a valvate æstivation; the petals equal in number to the sepals and much larger; the stamens hypogynous, double the number of the petals, with anthers 2- or 4-celled, opening by a pore at the apex; ovary 2-celled, with a simple style and stigma; seeds pendulous, and furnished with a caruncle at the apex; albumen fleshy, in the axis of which lies a straight cylindrical embryo.

This is an order of Australian plants, containing but two genera, *Tetratea* and *Tremandra*.

Tetratea glandulosa.

1, cutting with flowers; 2, ovary with simple stigma; 3, 4-celled anther; 4, anther opening by a simple pore; 5, section of capsule showing its two cells; 6, seed with the caruncle and embryo lying in albumen.

TREMATODA. [ENTOZOA.]

TREMELLA. [TREMELLINI.]

TREMELLINI, the name of the last order of the Cohort *Hymenomyces* in Fries's arrangement of the natural order *Fungi*. The type of this order is the *Tremella*, a genus constituted by Dilleuius, and applied to a variety of forms of *Fungi* belonging to this group, but now arranged under other genera. The *Tremella* of Dilleuius included all kinds of the lower forms of plants which possessed a gelatinous character; and as these exhibited a tremulous motion on being shaken, he gave them this name. It was for a long time a matter of dispute among botanists as to where the *Tremellæ* should be placed. Linnaeus arranged them with the *Alga*, Persoon with the *Fungi*, and Smith as *Alga Ambigua*. As however their nature became better understood, many anomalous forms were removed from among them; and several genera having been formed, they are now arranged among the *Fungi*.

The plants of this order are known by their amorphous character, having a soft gelatinous appearance, and looking like gummy exudations of the substances on which they grow. Their sporidia are free. They have been at various times objects of superstition, and have also been employed in medicine. In the wooded countries, where they are

very common, the people call them Witch-Guts, Witch-Meat, and Witebes'-Butter.

The genus *Tremella* is known by its receptacle being gelatinous, homogeneous, bearing fruit all round, and destitute of papillæ. The sporidia are subergent. It has a large number of species, of which nine are known as British. They are all of them found on the decaying branches, trunks, and stumps of trees.

The genus *Exidia* is known by possessing a gelatinous homogeneous receptacle, covered above only with a papillate hymenium. The most remarkable species of this genus is the *Exidia Auricula Juda*, Jew's Ear. It has obtained its common name from its resemblance whilst growing to a human ear. The whole plant is sessile, concave, and flexuous, of a leathery consistence, and a reddish-brown colour. It is found mostly on living trees, especially the elder. It is generally from one to three inches wide. This plant was at one time held in much repute for its medicinal properties. It has an astringent character, and has been used in infusion as a lotion in ophthalmia, and also as a gargle in sore throat. It has also been used in the same cases as a poultice.

E. glandulosa, Glandular Exidia, or Witches'-Butter, is an effused mass more or less plane, thick, and undulated, varying from a whitish-brown to a black colour; the hymenium is covered with spicules.

The genus *Dacrymyces* has a gelatinous homogeneous receptacle filled within with suberect flocci, and interspersed sporidia. This genus, sometimes called Tear-Mould, yields species which attack wrought wood, and produce what is called dry-rot. The *D. moriformis*, Mulberry Tear-Mould, is of a rich deep purple colour, and is found on wrought wood in a clustered rounded form resembling a mulberry.

There are three other genera belonging to the order Tremellini—*Nematelia*, *Aggrium*, and *Hymenula*: they have each one species, and all of them were formerly described under the genus *Tremella*.

TREMOLITE. [HORNLENDE.]

TREPANG. [HOLOTHURIDÆ.]

TRETOSTERNON. [CHELONIA.]

TREWIACEÆ, a natural order of Plants belonging to the Rectembryose group of incomplete Exogens. This order has for its type a single genus, *Trewia*, which was named after Christopher James Trew, a physician of Nürnberg. The species are but few: they are trees with opposite and stipulate entire leaves and dioecious flowers: the antheriferous flowers are arranged in long racemes, and the pistilliferous flowers are axillary and solitary. The calyx in both flowers is 3-4-cleft; the stamens are numerous; the style is 4-cleft; the fruit is a drupe, 4-celled, with one seed in each cell.

The plants of this order are natives of tropical India, and their properties are at present unknown, nor is their structure well understood. *Trewia* is mostly referred to *Euphorbiaceæ*.

TRIÆNODON. [SQUALIDÆ.]

TRIAKIS. [SQUALIDÆ.]

TRIANTHEMA, a genus of Plants of the natural order *Portulacææ*, so named from *τρίς*, three, and *ἄνθος*, a flower, in consequence of the flowers growing in threes, in the axils of the leaves. The species occur as weeds in every part of the plains of India. *T. obcordata*, like the plants of the family to which it belongs, is employed by the natives of India as a potherb; but the nauseous and bitter roots of *T. monogyna* are said by Dr. Ainslie to be employed as a purgative by the inhabitants of Hindustan.

TRIBULUS (*τρίβολος*, three-spiked or pointed), a genus of Plants belonging to the natural order *Rutaceææ*, the fruit of which is armed with prickles. It has a 5-parted calyx; petals 5, spreading; stamens 10; ovary superior; capsules 5, gibbous, spiny, many-seeded. The species are found in the south of Europe and the subtropical and tropical parts of the world, with diffuse, often procumbent stems, with solitary white or yellow flowers in the axils of the leaves. *T. terrestris* is sometimes cultivated in the gardens of the West Indies on account of the sweet scent of its flowers. This, as well as *T. cistoides*, has some aperient properties ascribed, and is therefore sometimes used medicinally in the countries where it is indigenous. [TRAPA.]

TRICHAS. [SYLVIADÆ.]

TRICHECHUS. [PROCIDÆ.]

TRICHIA. [TRICHOSPERMI.]

TRICHILLIA, a genus of Plants belonging to the natural order *Meliaceææ*. This species are found in the tropical parts of America, and a few in Africa and in Australia. An Indian species, *T. spinosa*, is not well known, but the oil of its seeds is said to be a useful remedy in chronic rheumatism and paralytic affections. Several are possessed of active properties. Forskal found the fruit of one species in the mountains of Yemen used as an emetic, and called *Jouzal-Cai*, or the Emetic Nut, whence he named it *Elcagl*, now called *T. emetica*. The seeds bruised are used for washing the hair, as well as an application in itch. *T. trifoliata*, a native of Curaçoa, has an unpleasant smell in all parts, and is said to possess active properties. *T. cathartica* is described by Martius as having great bitterness, and as employed in Brazil as a cure for fevers, &c. *T. moschata* is remarkable in Jamaica for the odour of musk which it diffuses all around, on which account it is called Musk-Wood.

TRICHINA. [ENTOZOA.]

TRICHIURUS. [TENUIOIDES.]

TRICHOCEPHALUS. [ENTOZOA.]

TRICHODERMA'CEÆ, a tribe of Plants belonging to the sub-order *Gasteromyceles*, of the natural order *Fungi*.

TRICHODESMA (from the root *τριχο*, hair, and *δέσμος*, a bond), a genus of Plants belonging to the natural order *Boraginaceææ*. The species have little beauty and are of little use. *T. Indica* and *T. Zeylanica* are reputed in India to have diuretic properties, but are probably only demulcent. They are likewise reckoned among the numerous plants which are supposed to have the power of curing the bites of snakes, but probably possess no other power than what they derive from their mucilaginous nature.

TRICHOGLOSSUS. [PEITTACIDÆ.]

TRICHOMANES. [HYMENOPHYLLIDÆ.]

TRICHONE'MA, a genus of Plants belonging to the natural order *Iridaceææ*. It has a regular 6-cleft perianth, with spreading segments; the three stigmas are bifid; the lobes slender. *T. Columbe* is the only British species; it has a solitary 1-flowered nodding scape; filiform compressed leaves; the spathe longer than the tube of the corolla; the style shorter than the stamens. The flower is pale purple or violet, with a yellow centre. It is found in sandy places in Jersey and Guernsey. (Babington, *Manual of British Botany*.)

TRICHOPHORUS. [MERULIDÆ.]

TRICHOPHYTON. [ENTOPHYTA.]

TRICHOPTERA. [NEUROPTERA.]

TRICHOSANTHIS, a genus of Plants belonging to the natural order *Cucurbitaceææ*. Many of the species are edible, and from the long often sinuous-formed fruit they have been named Snake-Gourds; the *Anguria* of some botanists. The fruit of many of the species is eaten in India, whilst that of others contains a purgative principle.

TRICHOSPERMI, a tribe of Plants belonging to the sub-order *Gasteromyceles*, of the natural order *Fungi*. It is known by its peridium being single or double, bursting when full grown, and pouring forth abundant naked dust-like sporidia. The sporidia are subglobose and rather large, and are collected more or less in the centre of the peridium, and are loose or interwoven with the flocci. The genera belonging to this order are rather numerous, and are divided into *Trichogastres*, those having a fleshy consistence, and *Myxogastres*, those having a soft and mucilaginous consistence.

To the first division belong all those forms of *Fungi* which are popularly known as Puff-Balls, Blind-Man's-Buff, Devil's Snuff-Boxes, &c. They have obtained these names on account of the property they possess of giving out when in a ripened state the sporules with which their interior is filled. These sporules are so exceedingly small and light, that on the peridium, or external covering of the plant, being broken, they rise into the air like smoke. Many of these sporules do not measure more than from $\frac{1}{10000}$ th to $\frac{1}{20000}$ th of an inch in diameter. They possess a curious property of repelling the particles of water, so that if the surface of a basin of water is covered with them, the band may be plunged to the bottom of it without being wetted. [BOVISTA; LYCOPERDON; FUNGI.]

TRICHOSTOMA. [NEUROPTERA.]

TRICHO'TROPIS (from the root *τριχο*, hair, and *τρόπις*, a keel), a genus of Gasteropodous *Mollusca*.

The shell is turritated and carinated externally; the aperture wide, but still longitudinal and rather longer than the spire, its base entire without any notch, although immediately below the obliquely truncated base of the columella there is an indistinct canal. The whole shell is thin and delicate, the outer lip especially. Epidermis bony, forming numerous sharp-pointed bristle-like processes on the edges of the carinae outside the shell, very strong, and by its contraction in drying frequently breaking the edge of the lip.

Operculum horny, much smaller than the aperture, composed of elliptical laminae; its apex or nucleus lateral. Animal resembling in most particulars a *Buccinum*.

But two or three species of this genus are known.

Trichotropis bicarinata. a, operculum.

TRICKLASITE. [FARLUNITE.]

TRICOCCÆ, the name of a natural order in the 'Fragments of a Natural System' of Linnaeus. *Euphorbia* was selected by Linnaeus as the type of this order. [EUPHORMIACEÆ.]

TRICONDYLA. [CTENOSTOMA.]

TRIDA'ENA. [TRIDACNIDÆ.]

TRIDA'CNIDÆ, a family of Conchiferous *Mollusca* comprising the genera *Tridacna* and *Hippopus*.

Tridacna.—Animal oval, cordiform, having the lobes of the mantle united nearly throughout the circumference: three apertures; two

posterior and inferior for the anus and for respiration, the third anterior, corresponding with the gape of the lunule, and giving passage to a thick, cylindrical, and byssiferous foot, in nearly all the species. Mouth oval, furnished with great lips, at the extremity of which are two pairs of pointed labial palps. (Deshayes.)

Shell regular, equivalve, inequilateral, transverse; with a gaping lunule. Hinge with two compressed, unequal, anterior, and intrant teeth. Ligament marginal, external. (Lamarck.)

T. gigas. Shell very large, transversely oval, with great imbricated ribs, the scales shot, arched, and lying near together; the interstices of the ribs not striated.

Tridacna gigas.

Tridacna hippopus.

The size and weight of this immense bivalve, the largest and heaviest known,* combined with the beautiful marble-like appearance and whiteness of the inside of the valves, have always caused it to be sought for as an ornament for grotto-work or for garden-fountains; and, indeed, the valve of a large individual forms a very picturesque basin for catching the clear falling water and transmitting it through the deep interstices of its indented edge to the reservoir below. Wolfart's fossils were not improbably the relics of some ancient and long-neglected pleasure-ground. The specimen whose valves serve for holy-water vessels (Béutiers) in the church of Saint Sulpice was presented to Francis I. by the republic of Venice; and Lamarck observes that, large as these are, still larger have been known.

This species can hardly have been the *Tridacna* of Pliny ('Nat. Hist.' xxxii. 6), which was probably only some overgrown European oyster that required three bites. A fine well-fed Indian giant *Tridacna* would furnish forth a dish for a dozen. But it is not improbable that the *Pedalia*, or oysters a foot long, from the Indian Sea, noticed in the preceding sentence of the same book and chapter, may have been *Tridacna* of modern authors.

The figure of *T. gigas* given in the 'Zoology of the Astrolabe' was designed at Carteret Harbour, New Ireland. The natives brought many very large individuals, whose flesh was abandoned to them, and which they ate raw. The naturalists of the expedition found the species again at Tongataboo, at the Moluccas, at Timor, and at Wagiau. It appeared always to inhabit rather shallow water.

Some fine specimens are to be seen in the Garden of the Zoological Society, Regent's Park.

T. hippopus (*Chama hippopus*, Linn.; *Hippopus maculatus*, Lam.; *Tridacna maculata*, Quoy, 'Voyage of the Astrolabe.')

This well-known but beautiful species, now much used in the ornamental arts for inkstands, &c., has a transversely ovate shell, which is of moderate size, ventricose, ribbed, subsquamous, and white spotted with red or purple; the lunule is heart-shaped and oblique.

The naturalists of the 'Voyage of the Astrolabe' found this species at Carteret Harbour, New Ireland, and also at Vanikoro, where they collected specimens left dry on the reefs.

TRIDACOPHYLLIA. [MADREPHYLLICEA.]

TRIDACTYLUS, a genus of Orthopterous Insects, belonging to the family Gryllidæ. They are minute exotic insects, fossorial in their habits, using the anterior tibiae. The posterior tarsi are replaced by narrow bent moveable appendages. The antennæ are very short, and 10-jointed.

TRIENANTHUS, a genus of Plants belonging to the natural order Primulaceæ. In British botany this genus is somewhat conspicuous, as it is the only one which belongs to the Linnæan class Heptandria. The parts of the fructification are remarkable for being arranged according to the number seven.

T. Europæa, the European Chick-Weed, Winter-Green, is a British species. It is distinguished from the American species by possessing elliptical instead of lanceolate leaves. This plant is rare in England, being only occasionally met with in woods in the northern counties; it is however abundant in many parts of the Highlands of Scotland.

T. Americana, the American Chick-Weed, Winter-Green, has lanceolate leaves. It is found in mountainous districts in Canada and Virginia.

TRIFOLIUM (τρίφυλλον), a genus of Plants belonging to the natural order Leguminosæ. This genus, which has obtained its Latin as well as its French and English designations, Trefle and Trefoil, from its leaves possessing three segments, is one of the most extensive in the vegetable kingdom. The calyx is tubular, 5-cleft; corolla remaining after decay; carina obtuse; stamens diadelphous, more or less connate with the petals, the filaments dilated above; the style smooth; legume ovate, with one or two seeds, sometimes oblong, with three or four seeds, and included within the decaying calyx and corolla. All the species are herbs. The leaves are mostly divided into three segments or foliolules; sometimes they are seen with four or five. The flowers are disposed in dense heads or spikes, and are of a purple white or cream-colour. De Candolle has arranged the numerous species of this genus under seven sections, the characters of which are founded principally on the inflorescence and on the form of the calyx, or of the corolla combined with it. We shall here select some of the most useful and remarkable of the species as illustrations of the genus.

T. incarnatum, Flesh-Coloured Trefoil, or Scarlet Clover. The spikes of flowers are at first ovate, at length cylindrical, solitary, and naked at the base; the calyx 10-nerved and hairy, with unequal awl-shaped acute teeth, longer than the tube and shorter than the corolla; stipules ovate and obtuse; leaflets obovate, creunated, villous; stem erect. The species is a native of the south of Europe, in damp meadows. [CLOVER, in ARTS AND SC. DIV.]

T. arvense, Hare's-Foot Trefoil. The stem erect, branched, or simple; heads of flowers very hairy, soft, nearly cylindrical, terminal, stalked; the teeth of the calyx longer than the corolla, setaceous, and somewhat spreading; stipules ovato-acuminate; leaflets lanceolate, obtuse. This plant is a native of Europe, and is abundant in corn-fields and dry pastures in Great Britain. Its soft hairy subcylindrical heads or spikes give it a very remarkable character.

T. maritimum, Sea-Side or Tassel-Headed Trefoil. The heads are

* Five hundred pounds have been recorded as its weight.

sessile and terminal; the teeth of the calyx broad, acuminate, rigid, the lower one much longer and larger than the rest, shorter than the claws of the petals, all of them at length enlarged and spreading; stipules lanceolate-subulate; leaflets oblongo-obovate; stem ascending. It is a native of Europe, in salt marshes and meadows near the sea-side. It is found on the east and south coasts of Britain.

T. Alexandrinum, Alexandrian Trefoil, or Clover, is a native of Egypt, about Alexandria. It is the only Trefoil that is cultivated in Egypt, where it is extensively used as fodder for cattle.

T. medium, Meadow-Trefoil, Marl-Clover, or Cow-Grass. The heads of the flower are lax, subglobose, solitary, terminal; the teeth of the calyx are setaceous, the lower one longer than the rest, about equal to the tube of the corolla; stipules lanceolate, acuminate; leaflets elliptical; stems branched, zigzag. It is a frequent plant in the pastures of Britain, where it can be recognised by its zigzag stem, from which circumstance it is sometimes called Zigzag-Trefoil.

T. pratense, Common Purple-Trefoil, or Red-Clover. The stem is ascending; the leaflets are oval or obcordate; the heads of flowers are dense and ovate; the teeth of the calyx are setaceous, the lower one longer than the rest; stipules ovate, bristle-pointed. This plant has reddish-purple flowers, and is frequent in meadows and pastures, where it blooms all through the summer. The leaves are usually marked with a white subsagittate mark in the centre.

T. repens, White-Trefoil, White- or Dutch-Clover. It has umbellate globose heads; legumes with four seeds; teeth of the calyx unequal; the leaflets obcordate, serrulate; the stem creeping. This plant is said to be the Shamrock of Ireland, and is worn by the Irish as the badge of their country. The original Shamrock does not appear to have been a clover, but the *Oralis acetosella*, which has also leaves with three divisions. Leaves of this character have, from a very remote period, been regarded with superstitious reverence.

"The holy trefoil's charm"

was supposed to be very "noisome to witches," and to keep those who wore it from the influence of evil spirits of all kinds.

T. suffocatum, *T. glomeratum*, *T. subterraneum*, *T. fragiferum*, are all British species.

TRIGLA, a genus of Acanthopterygious Fishes, popularly known as Gurnards, and belonging to the family *Loricati* in the arrangement of Cuvier.

The head of *Trigla* is mailed and angular; the opercle and shoulder-bones armed with spines; the body is scaly; there are two distinct dorsal fins; beneath the pectorals are three detached rays; the branchiostegous membrane has seven rays; both jaws and the front of the vomer are armed with fine velvety teeth. The Gurnards are fishes always remarkable for singularity of form, and often for brilliancy of colouring. They derive their popular appellation from a grunting noise which they make when taken out of the water. In the British seas the commonest species are the Gray Gurnard (*Trigla Gurnardus*), a silvery gray fish more or less clouded with brown and speckled with black; the Red Gurnard (*Trigla Pinn*), of a bright rose-red colour; and the Sapphirine Gurnard (*Trigla Hirundo*), a large and handsome fish remarkable for the vivid green and blue hues of the inner surface of its large pectoral fins. The two last are most abundant in the western coasts. Several other rarer species are also inhabitants of the British seas. There are some beautiful small species in the Mediterranean, where also lives the Flying-Gurnard (*Dactylopterus volitans*), which differs generically from *Trigla* in having the fin-rays of the pectorals connected by membranes, by means of which the fish is enabled to support itself for some time in the air in the manner of the flying-fish. It is a handsome species, above a foot long. Another Flying-Gurnard (*Dactylopterus Orientalis*) lives in the Indian Ocean.

TRIGLOCHIN (τριγλῶν, three-pointed), a genus of Plants belonging to the natural order *Juncaginaceae*. It has a perianth with six concave deciduous leaves, three outside and three inside; the anthers are sessile, lodged in the leaves of the perianth, and have their backs turned towards the ovary; the capsules are from three to six in number, are 1-seeded, and united by a longitudinal receptacle, from which they separate at the base. The genus has several species: they are inhabitants of marshes, sides of rivers, ditches, and wet meadows. Two only of the species inhabit Europe, and these are found in Great Britain.

T. palustre, the Marsh Arrow-Grass, has a 3-celled fruit, of a linear form, attenuated towards the base. It grows in damp marshy places, and is very abundant in many parts of this country.

T. maritimum, Sea-side Arrow-Grass, has a 6-celled ovate fruit.

TRIGLOCHIS. [SQUALIDÆ.]

TRIGONELLA (from τρεῖς, three, and γωνία, an angle), a genus of Plants belonging to the natural order *Leguminosae*. It consists of strong-scented herbs with trifoliate leaves; the calyx is 5-parted and 5-toothed; the keel of the corolla is obtuse; the stamens are diadelphous; the style is smooth; the fruit a legume, unilocular, compressed, linear, and containing six or more seeds. The known species of this genus are upwards of thirty. Only five of them are European, and only one is found in Great Britain.

T. Foenum-Grecum, the Common Fenugreek, has the stem erect, simple; the leaflets obovate, slightly toothed; the stipules lanceolate, falcate, entire; the calyx hairy; the teeth awl-shaped, of the length

of the tube; the legume is falcate, many-seeded; the seeds large, ovate, wrinkled from dots; radicle of cotyledons prominent. This plant is a native of the south of Europe. Dr. Sibthorp found it in abundance on the shores of Asia Minor. This plant, or one of the genus, was known to the Greeks under the name 'Hódopon, and to the Romans as Foenum Grecum, Greek Hay, and the seed was held in great esteem as a mediocr. The scent of the seeds is very strong, and it was undoubtedly this circumstance that recommended them to notice as medicinal agents.

T. ornithopodioides, the Bird's-Foot Trefoil, has a decumbent stem; the leaflets toothed at the extremity, the flowers three together; the legumes naked, twice as long as the calyx, with about eight seeds in each. This is the *Trifolium ornithopodioides* of Linnæus.

T. dlatior, Tall Fenugreek, has an erect stem; stipules lanceolate, toothed; legumes racemose, pendulous, linear, slightly curved, obtuse, longer than the leaves. Dr. Sibthorp found this plant in Asia Minor and the Isle of Cyprus, and Sir J. E. Smith is of opinion that it is the *Λότος Ἀγριος* of Dioscorides.

T. esculenta, Esculent Trigonella, has pedunculated racemes, with the peduncle longer than the leaf; the legumes are linear, somewhat curved, crowded together, and pedicellate. This plant is a native of some parts of the East Indies, where its legumes are eaten by the natives as food.

TRIGONELLI'ES, an obscure genus of Fossil *Mollusca*, to which many names have been applied, as *Aptychus*, *Ichthyosagones*, &c. It contains several forms which undoubtedly appertain to *Cephalopoda*, and offer analogies to a part of the *Sepiostemum*, and a part of the *Belemnite*.

TRIGON'IA. [TRIGONIDÆ.]

TRIGON'IDÆ, a family of Conchiferous *Mollusca*, the type of which is the genus *Trigonia*, Brug.

Trigonia has the following characters:—Animal having the mantle open along its length; no posterior tubes; foot powerful and trenchant.

Shell thick, nacreous, subtrigonal, equivalve, inequilateral, the umbones rather small and but little recurved; hinge complex, dissimilar, the right valve having two great oblong teeth, diverging from the umbo, strongly furrowed, penetrating into two excavations, of the same form and equally furrowed, in the left; ligament external; muscular impressions not united by a pallial impression. (Bang.)

T. margaritacea. Shell suborbiculate, nacreous within, ribbed externally with elevated verrucose somewhat sharp ribs, disposed in rays; margin plicated.

This species, which has only been found in the seas of Australia, appears to be of moderate size. Lamarck compares its external appearance to that of a nautilus without ears. It has been found at depths ranging from 6 to 14 fathoms, on sandy mud.

The fossil species are numerous, especially in the Chalk.

Trigonia margaritacea.

TRIGONIDÆ. [RAIDÆ.]

TRIGONOCARPUS. [COAL-PLANTS.]

TRIGONOCEPHALUS. [CROTALIDÆ.]

TRILLIACEÆ, *Paridis*, a small natural order of Plants belonging to the class *Dietyogens*. They are distinguished by their bisexual tripetaloidous flowers, half-consolidated carpels, and axile placentæ. Lindley gives the relations of this order with *Smilacaceæ*, *Roxburghiaceæ*, *Commelynacæ*, and *Melastomaceæ*. It contains 4 genera—*Paris*, *Demi-doria*, *Trillium*, and *Medeola*. [PARIS; TRILLIUM.] The species are found in thickets in the temperate parts of Europe, Asia, and North America. (Lindley, *Vegetable Kingdom*.)

TRILLIUM, a genus of Plants, the type of the natural order *Trilliaceæ*. It has 3 herbaceous sepals, 3 coloured petals, and 3 sessile stigmas. The berry is superior and 3-celled; the cells many-seeded.

T. erectum has a large proemorse rhizoma with thick horizontal fibres. The stem is about a foot in height, and sheathed at the base; the leaves large, acuminate, and sessile; the peduncle about half as long as the leaves, inclining to one side. The flower is large, and of a dark purple.

TRILOBITES, a race of extinct Fossil Animals. The forms of this animal were at first known by the name of the Dudley Fossil and the Dudley Fossil Insect. By some it was regarded as an insect, and called *Entomolithus paradoxus*; by others the form was considered as that of an extraordinary Testacean with a shell of three lobes; whilst others thought that the Trilobitic remains belonged to animals closely

approximated to the Chitons, or at least not differing greatly from them.

It is now agreed on all hands that Trilobites are Crustaceans.

The names imposed on some of the genera indicate the difficulties originally felt in understanding their structure.

Thus we have *Asaphus* (ἀσαφής, 'obscure'); *Calymene* (κεκάλυμμένη, 'concealed'); *Paradoxus* (παράδοξος, 'wonderful'); *Cryptonymus* (κρύπτω, 'to conceal'); *ἄνομα*, 'a name'; and *Agnostus* (ἀγνωστος, 'unknown').

Dr. Buckland ('Bridgewater Treatise') expresses an opinion that the nearest approach among living animals to the external form of Trilobites is that afforded by the genus *Serolis*. [ISOPODA.] He thinks that the most striking difference between this animal and the Trilobites consists in there being a fully developed series of crustaceous legs and antennæ in the *Serolis*, whilst no trace of either of these organs has yet been discovered in connection with any Trilobite. Brongniart, he observes, explains the absence of these organs, by conceiving that the Trilobites hold precisely that place in the Gymnibranchiate Crustaceans, in which the antennæ become very small, or altogether fail; and that the legs, being transformed to soft and perishable feet bearing branchiæ, were incapable of preservation.

A second approximation to the character of Trilobites occurs, according to Dr. Buckland, in the *Limulus*, or King-Crab (*Xiphosurus*), and he sees a third example of this disposition in *Branchipus stagnalis*. [BRANCHIOPODA; CHIROCEPHALUS.]

Mr. W. S. MacLeay, in his highly-interesting paper entitled 'Observations on Trilobites, founded on a comparison of their structure with that of Crustacea,' published in Sir Roderick Murchison's work on 'The Silurian System' (1839), points out the relations of these creatures with the Crustacea.

M. Milne-Edwards, in his 'Histoire Naturelle des Crustacés' (1840), expresses his belief that the Trilobites ought to be arranged between the *Isopoda* and the *Branchiopoda*. In all probability they belonged, he thinks, to the great division *Branchiopoda*.

Burneister, one of the latest writers on the subject of Trilobites, concludes that their structural relations are with the *Phyllopora*, amongst the Entomostracous Crustacea. He thus concludes his work on the organisation of Trilobites [ENTOMOSTRACA]:—

"The *Phyllopora* live in stagnant fresh-water, especially in ditches, pools, or puddles, which are very rapidly produced after rain in the early part of the year, and last only till the middle of the summer, when they become dried up. During this period the animals of the tribe we are describing are usually seen in numerous companies, swimming about in the water at various depths, the species of *Branchipus* being most frequently close beneath the surface of the water. In swimming they turn their back downwards, their abdomen being upwards, so that the feet touch the surface of the water. The position of the eyes in *Branchipus* enables the animal to look both upwards and downwards. *Apus*, on the other hand, which has immovable eyes, can only look downwards while swimming on its back, and it must turn itself if it wishes to look upwards. But this is quite natural, since in each case the animal, when in its usual position, and close beneath the surface of the water, can only have its enemies below, and therefore only needs to be secured against surprise in that direction. These creatures are however not much exposed to attack. Their prey, which consists of other little animals living in the water, they obtain during their constant swimming motion, and it is brought to the mouth by the motion of the water. Owing to this, the region and cavity of the mouth in many of these animals, when preserved in spirits of wine, are frequently entirely covered or filled up with extraneous substances.

"The *Phyllopora* are never at rest, partially because they are entirely deficient in organs by which they could keep firm hold of anything, partially also because their motion of swimming produces at the same time the motion of the respiratory organs, which being independent of the will of the animal does not cease. I have not yet had an opportunity of observing *Limnadia* and *Estheria* in a living state, but both genera undoubtedly exist in the same manner. I am not however aware whether they swim on their back. Considering the affinities of the Trilobites with the *Phyllopora*, I cannot doubt for a moment that their habits during life and their mode of existence were similar, and I therefore conclude:

"1. That these animals moved only by swimming, that they remained close beneath the surface of the water, and that they certainly did not creep about at the bottom as M. Klöden supposed.

"2. That they swam in an inverted position, the belly upwards, the back downwards, and that they made use of their power of rolling themselves into a ball as a defence against attacks from above.

"3. That they lived on smaller water animals, and in the absence of such on the spawn of allied species.

"4. That they most probably did not inhabit the open sea, but the vicinities of coasts, in shallow water, and that they lived gregariously in vast numbers, chiefly of one species.

"5. That the number of species could never have been very great. This is indeed proved by the mode of their appearance in the fossil state, inasmuch as scarcely more than six or eight species have been found together anywhere in one stratum.

"6. Although the number of species has not been large, the number

of individuals was very great indeed, a fact likewise observed in the living *Phyllopora*, of which we as yet scarcely know a dozen species, although these are grouped into about six different genera.

"7. The great differences existing in the dimensions of the present *Phyllopora* according to their age, justify us in expecting such differences also among the Trilobites, and very large individuals of the latter therefore do not indicate a separate species, unless other differences are presented."

Dr. Buckland in his observations on the 'Eyes of Trilobites,' a point, as he says, deserving peculiar consideration, as it affords the most ancient and almost the only example yet found in the fossil world of the preservation of parts so delicate as the visual organs of animals that ceased to live many thousands and perhaps millions of years ago, remarks, that we must regard those organs with feelings of no ordinary kind, when we recollect that we have before us the identical instruments of vision through which the light of heaven was admitted to the sensorium of some of the first-created inhabitants of our planet. After referring to the labours of Professor Müller and Mr. Strauss, who have ably and amply illustrated the arrangements by which the eyes of insects and Crustaceans are adapted to produce distinct vision through the medium of a number of minute facets or lenses placed at the extremity of an equal number of conical tubes or microscopes, amounting sometimes, as in the Butterfly, to 35,000 facets in the two eyes, and to 14,000 in the Dragon-Fly; Dr. Buckland remarks that in eyes constructed on this principle, the image will be more distinct in proportion as the cones in a given portion of the eye are more numerous and long; and that as compound eyes see only those objects which present themselves in the axes of the individual cones, the limit of their field of vision is greater or smaller as the exterior of the eye is more or less hemispherical. The same principles of construction as to form, the disposition of facets, and optical adaptation, are obvious in the eyes of Trilobites.

Back of *Asaphus caudatus* (Dudley, Mus. Stokes), with the eyes, *a a*, well preserved. (Buckland.)

a, side view of the left eye of the same, magnified. (Buckland.)

b, magnified view of a portion of the eye of *Calymene macrophthalmus*. (Haeckel.)

According to Dr. Buckland each eye of *Asaphus caudatus* contains at least 400 nearly spherical lenses fixed in separate compartments on the surface of the cornea, and he observes that the form of the general cornea is peculiarly adapted to the uses of an animal destined to live at the bottom of the water: "to look downwards was as much impossible as it was unnecessary to a creature living at the bottom; but for horizontal vision in every direction the contrivance is complete. The form of each eye is nearly that of the frustum of a cone, incomplete on that side only which is directly opposite to the corresponding side of the other eye, and in which, if facets were present, their chief range would be towards each other across the head, where no vision was required. The exterior of each eye, like a circular bastion, ranges nearly round three-fourths of a circle, each commanding so much of the horizon, that where the distinct vision of one eye ceases that of the other begins; so that in the horizontal direction the combined range of both eyes was panoramic."

M. Milne-Edwards, addressing himself to the subject of antennæ, observes that, as in *Apus*, one perceives no trace of those organs when the Trilobites are seen from above or viewed on their dorsal aspect, and that if any vestiges of those appendages exist, they will probably

be found on the lower surface of the head on each side of the mouth, as in the *Phyllopoda*; but he is compelled to admit that no specimen has yet been discovered which showed the slightest trace of them, remarking that there would be nothing astonishing if the antennæ, become already rudimentary and reduced to two in *Apus*, should in the Trilobite be entirely wanting.

The same author calls attention to the sutural lineation, termed by him the jugal line, which exists on each side of the upper surface of the head, and is more or less flexuous, springing from the posterior border, passing along the eyes, and reaching the frontal edge.

The lower surface of the head is occupied in front by a flat surface, sufficiently resembling, in the opinion of M. Milne-Edwards, that which exists in *Apus* and *Limulus*, but which is divided by prolongations of the jugal sutures, into two or three pieces, according as these lines unite on the median line of the front before they are recurved downwards and backwards, or at least remain separated for a more or less considerable space. Behind this region traces of the buccal apparatus have been detected, though but little appears to be known relative to its conformation. Dekay, C. Stokes, and Sars, have found a plate or lamina bifurcated posteriorly, which, in the opinion of M. Milne-Edwards would seem to constitute a labrum, or epistomial piece analogous to that which gives insertion to the labrum in certain *Isopoda*.

Under surface of the anterior portion of the shield of *Asaphus platycephalus*, from Lake Huron. (Stokes.—See 'Geol. Trans.,' N.S., vol. 1., pl. 27.)

Dr. Buckland, in his 'Bridgewater Treatise,' speaks of the great extent to which Trilobites are distributed over the face of the globe, and their numerical abundance in the places where they have been discovered, as remarkable features in their history. He notices their occurrence at the most distant points both of the northern and southern hemisphere. "They have been found," says Dr. Buckland in continuation, "all over Northern Europe, and in numerous localities in North America; in the southern hemisphere they occur in the Andes and at the Cape of Good Hope. No Trilobites have yet been found in any strata more recent than the carboniferous series; and no other Crustaceans, except three forms which are also Entomostracous [SPONDYLIDE], have been noticed in strata coeval with any of those that contain the remains of Trilobites: so that during the long periods that intervened between the deposition of the earliest fossiliferous strata and the termination of the coal-formation, the Trilobites appear to have been the chief representatives of a class which was largely multiplied into other orders and families after these earliest forms of Marine Crustaceans became extinct."

The following is an outline of the arrangement of the species given in Burmeister's 'Organisation of Trilobites,' translated for the Ray Society, and edited by Professor Bell and the late Professor Edward Forbes:—

The *Palæada* are Crustaceous *Articulata*, belonging to the second order of the class *Crustacea* (divided into *Astracodermata*, *Aspidostraca*, and *Entomostraca*), characterised by the possession of two large compound eyes, by the absence of simple secondary eyes, and by having short undeveloped feelers, and soft leaf-formed feet, bearing gills. By these characters they are immediately related to the *Phyllopoda*, and might perhaps even be united with the latter in one tribe. Their principal difference would then consist in the absence of the constant numerical proportion of eleven rings of the thorax, common to all the *Phyllopoda*, which must be expressed by the formula of $4 \times 3 - 1$. Instead of this the *Palæada* exhibit fluctuating numerical proportions in the parts of the thorax, respecting the reduction of which to a constant formula nothing certain can be said, because we neither know the number of the accessory parts of the mouth, nor the position of the sexual openings. These animals underwent a progressive metamorphosis; they moved by swimming probably with their backs downwards, and they inhabited the ocean, living chiefly in shallow water. The whole group is divided into three families, which are characterised according to the nature of the shelly covering.

Family 1. *Eurypterida*.

In these there is no shell. The head, whose position is very distinct, bears two pairs of setaceous feelers, and one pair of accessory parts of the mouth. There are probably nine (?) rings in the thorax, the first of which bears a pair of very large rudder-shaped feet, furnished with

five joints; and the succeeding rings seem to have borne similar leaf-like feet of an equal size. The abdomen consisted of three or six rings, and was terminated by a pair of rudder fins. There is only one genus belonging to this family, *Eurypterus*.

Family 2. *Cytherinida*.

These animals were contained in bivalve bean-shaped shells, which are the only parts preserved. They are more or less pointed towards the external wider margin; at the straight or dorsal margin they are rather thickened. They vary in size from $\frac{1}{4}$ " to $\frac{3}{4}$ ", or even, though rarely, 1". The only genus is *Cytherina*.

Family 3. *Trilobita*.

The body covered by an affixed shell, which consists of as many rings as there are joints of the thorax (?). The head and the abdomen each similarly included in a large united shield, which, like the rings of the shell of the body, possesses a broad border that freely projects at the sides. The large eyes are situated in the lateral portions of the cephalic shield, remote from the true head. A peculiar suture passes through the cephalic shield, and divides it into two, three, or four special parts. The numerous members of this family which have been already described admit of a further division into natural genera, the most suitable classification of which may perhaps be the following:—

I. Trilobites incapable of rolling themselves up.

Group 1.—The lateral lobes of the rings of the body are situated in the same plane, and do not curve or bend downwards, but terminate towards the posterior part in a more or less prominent point, sometimes very long, which forms a somewhat obtuse angle in its principal direction with the direction of the lobe.

A. Trilobites with a simple large caudal shield (not much smaller than the cephalic shield), the axis of which is many-jointed, and equals, or even exceeds, the length of the body. *Ogygiida*. To this group belong two genera:—

1. *Trinnucleus*, with six rings.
2. *Ogygia*, with eight rings.

Trinnucleus Lloydii.

B. Trilobites having a simple though tolerably large caudal shield, the axis of which consists of but a few joints, and is always shorter than the body. The genera belonging to this division may be divided, according to the number of body-rings, into 8-jointed and 10-jointed.

3. *Odontopleura*.
4. *Arges*.
5. *Bronteus*.

C. Trilobites having a simple but very small caudal shield, the axis of which is many-jointed, but which is always shorter than the body.

6. *Paradoxides*.
7. *Olenus*.

Paradoxides Tessini.

Group 2.—The lateral lobes of the body-rings not horizontally extended in their whole length, but turned downwards from the centre, and not terminating in a point, but with an arched and rounded extremity. Furrowed on the surface along their whole length.

8. *Cenocephalus*.
9. *Ellipsocephalus*.
10. *Harpes*.

II. Trilobites having the power of rolling themselves into a ball.

Section 1. Trilobites having the power of rolling themselves up into a ball with the axis of the body constructed posteriorly, the shell granulated, and generally more than ten body-rings.

A. Trilobites capable of rolling themselves up, and whose facial suture terminates exactly in the angles of the cephalic shield.

11. *Calymene*.

12. *Homalonotus*.

Calymene Boeckingii, partially rolled up.

B. Trilobites having the power of rolling themselves up, whose facial suture terminates in the external lateral margin of the cephalic shield.

13. *Phacops*.

C. Trilobites capable of rolling themselves up, having the axis of the body diminishing posteriorly, and their facial suture extending to the posterior margin of the cephalic shield.

14. *Cyphaspis*.

15. *Proetus*.

16. *Archegonius*.

Section 2. Trilobites possessing the capacity of rolling themselves up; the body axis not shortened posteriorly; the shell finely lined; the caudal shield not having radiated lateral furrows.

A. The body-axis consisting of ten equal rings.

17. *Illæus*.

B. The body-axis consisting of nine rings.

18. *Dysplanus*.

C. The axis of the body consisting of eight equal rings.

19. *Asaphus*.

Asaphus (Nileus) Armadillo.

a, seen from above; b, profile, the animal rolled up.

D. Six-jointed Trilobites capable of rolling themselves up, and having the axis of the body equally broad throughout.

20. *Ampyx*.

In an appendix, Burmeister describes *Agnostus*, which is an anomalous form. The species are small, with nearly circular bucklers of two kinds, which M. Brongniart considers to have covered the whole of the body to which each of these discs belonged, and which Dalman regards as being only portions of the body, and as having belonged, some to the head, others to the abdomen, of a Trilobite whose thorax must have been reduced to a rudimentary state, or at least must have remained membranous. These two sorts of bucklers or shields have nearly the same form and size, but differ in the disposition of the eminences perceptible on their surface, and are divided into three lobes. The only species known is the *Agnostus* of Brongniart, *Buttus* of Dalman.

Agnostus pisiformis. (After Dalman.)

The following is a list of the British genera of Trilobites, with their number of species:—*Acidaspis*, 1 species; *Amphion*, 4; *Ampyx*, 4; *Agnostus*, 2; *Arges*, 1; *Asaphus*, 20; *Bronteus*, 2; *Bumastes*, 1; *Calymene*, 11; *Ceraurus*, 1; *Eurypterus*, 1; *Griffithides*, 4; *Hurpes*, 3; *Homalonotus*, 4; *Illæus*, 4; *Isoteles*, 10; *Nuttainia*, 2; *Ogygia*, 2; *Olenus*, 1; *Paradoxides*, 3; *Phacops*, 5; *Phillipsia*, 7; *Remopleurides*, 5; *Trinucleus*, 10.

In Mr. McCoy's 'Synopsis of the Carboniferous Fossils of Ireland,' the following new species are described and figured:—*Griffithides calcaratus*; *Phillipsia celata*; *P. Colii*; *P. discors*; *P. mucronata*; *P. quadriseriatis*.

In Mr. McCoy's 'Synopsis of the Silurian Fossils of Ireland,' collected by Mr. Griffith, the following new genera are described and figured:—*Forbesia*; *Portlockia*; *Tircsias*; *Trinodus*.

TRIMERA, the fourth section of the order *Colcoptera* among Insects, according to the arrangement of Latreille. The insects popularly known as Lady-Birds and Puff-Ball-Beetles are characteristic of the families composing it.

The insects of this division have four palpi, two of which are labial and two maxillary. These palpi are short and slender, or with an enlarged terminal joint. The antennæ are also short and thickened at their extremities, in some species gradually, in others suddenly. The body is oval or hemispheric; the head is not produced anteriorly, and is deeply inserted in the thorax, which is short and transverse, or somewhat square and flattened. The abdomen, generally flat beneath and ample, is covered by the elytra, which are arched, very convex, and never truncated at the tip. The legs are short, with tarsi apparently composed of three joints, but in reality of four, the second being bilobed, and concealing between its lobes a minute third joint, the seeming absence of which has given origin to the name of the section. Westwood, with more propriety, has styled the division *Pseudo-Trimera*.

Latreille divided the *Trimera* into three families, which he styles *Fungicole*, *Aphidiphagæ*, and *Pselaphii*. The last has however been united by English entomologists with the *Staphylinidæ*, to which insects their truncated elytra, too short to cover the abdomen, and general aspect, give them a great resemblance. Westwood includes among his *Pseudo-Trimera*, the *Clavipalpi*, the seventh and last family of *Tetramera* in Latreille's arrangement. He styles the family *Erotylidæ*, from the typical genus *Erotylus*. They are chiefly exotic insects, supposed to feed on vegetable matter; and were regarded by Latreille as connecting the *Cyclica* (*Cassida Chrysomela*) with his trimereous family *Fungicole*.

The *Fungicole* of Latreille (*Endomychidæ* of British authors) are so styled from their habitat in the interior of cryptogamic plants of the class *Fungi*, on which they feed. Some species are found under the damp bark of trees, where however their food consists of the *Fungi* which are peculiar to such a locality. The perfect insect is very convex, oval, and glabrous, and many of the species are ornamented with brilliant colours. The antennæ are composed of eleven joints thickened towards the extremity, and larger than the head and thorax. Their elytra cover the abdomen, and the penultimate joint of the tarsus is deeply bilobed. The only known larva of an insect of this family is that of *Endomychus coccineus*, said by Samouelle to resemble the common glowworm. Curtis figures it. Westwood remarks that it has more analogy to the larva of the *Silphidæ* than to that of the glowworm or of *Coccinella*. The British species of this family belong to the genera *Endomychus* and *Lycoperdina*. They are but few in number. One of them, the *Lycoperdina Bovista* is found in great numbers inhabiting that common puff-ball the *Lycoperdon Bovista*. *Eumorphus* is an American genus, described by Weber, distinguished by the dilated flattened three-jointed clubs of the antennæ. It includes several eccentric forms, in which the elytra have broad dilated margins with the anterior tibiae notched. Mr. Curtis considers them as related to those singular insects which constitute the genus *Mormolyce*, but Westwood regards the relation as one of the most remote analogy.

The *Aphidiphagæ* (*Coccinellidæ* of English authors) are animal-feeders preying upon Plant-Lice (*Aphides*), and correspond to the Linnæan genus *Coccinella*. In shape they are very convex and hemispheric, and have antennæ shorter than those of the last family, terminated by a compressed club in the form of a reversed triangle. The larva is depressed, ovate, and fleshy. The three anterior segments of its body are largest, and the abdominal ones tubercled and spotted. Its head is small, with very minute antennæ and thick maxillary palpi. The pupa is found attached by its posterior extremity to a leaf, and undergoes its metamorphosis in that position. The larva emits from its tubercles a yellowish fluid having a disagreeable scent. When the perfect insect is laid hold of, it gives out a similar secretion from its joints, and folds its legs up as if simulating death.

The insects of this family are remarkable for brilliant colouring, being generally red or yellow, with black, red, white, or yellow spots. Individuals of the several species are so extremely variable and different from each other in their markings, as to render the construction of specific diagnoses in this family more difficult than in any other tribe of *Colcoptera*. Some have supposed that many of these varieties are hybrids between the sexes of different species, but M. Audouin maintains that the eggs produced from the union of allied species in the genus *Coccinella* are sterile. They creep slowly, but fly well, and many kinds are gregarious. The eggs are deposited in yellow patches among the plant-lice, so that the larva is hatched in the midst of its food. They abound in our fields and gardens, and are among the first beetles which come out in spring. They appear sometimes in immense swarms, and spreading over the fields cause needless alarm to the farmer, to whom, far from being a pest, they are a blessing, from the fierce war they wage against his enemies the *Aphides*.

The peasants in France style them 'Bêtes-à-Dieu,' honouring their useful qualities; whilst the English name of Lady-Bird does homage to their beauty. Some of the species are widely distributed, such as the very common *Coccinella septempunctata*, which extends its range over all Europe and parts of Asia and Africa. In England we have six genera of *Coccinellidae*, and more than fifty species.

TRIMESURUS. [CROTALIDÆ.]

TRINGA. [CHARADRIADÆ; SCOLOPACIDÆ.]

TRINIA, a genus of Plants belonging to the natural order *Umbellifera*, named after Dr. C. B. Trinius of St. Petersburg. The species of this genus, which are not numerous, have been referred to *Pimpinella* and *Scadi*, but the dioecious flowers and the difference between the structure of the petals in the barren and fertile flowers render it very distinct. One of this species, the *T. glaberrima*, Smooth Honewort, is an inhabitant of Great Britain, but must be looked upon as a rarity. It has been found on limestone in Somersetshire, Cornwall, and Devonshire. The whole plant is of a pale glaucous green colour, has remarkable segments of the leaves, which are tripinnate; no involucre. It appears to be the same plant as the *T. vulgaris* of De Candolle, which is found in the southern parts of Germany, in Switzerland, and Austria.

TRINU'CLEUS. [TRILOBITES.]

TRIO'DIA, a genus of Grasses belonging to the tribe *Avenineæ*. The glumes are from 2- to 3-flowered; the outer palea rather coriaceous, smooth, rounded on the back, bifid, with an intermediate broad point sometimes becoming the base of a kneed awn. *T. decumbens* is found in mountain pastures in Great Britain.

TRI'ODON. [GYMNODONTES.]

TRIONYX. [CHELONIA.]

TRIOPTOLEMÆA. [TRIPTOLEMÆA.]

TRIOSTEUM (from *τρεῖς*, three, and *ὀστέον*, a bone, in reference to the three bony ends in each berry), a genus of Plants belonging to the natural order *Caprifoliaceæ*. It has a calyx, with an ovate tube and a 5-parted permanent limb, with linear lanceolate permanent lobes. The corolla is tubular, almost equally 5-lobed, gibbous at the base, and longer than the calyx. The stamens are 5, and inclosed; the stigma oblong and thick; the berry coriaceous, obovately triquetrous, crowned by the calyx, 3-celled, and 3-seeded. The species are permanent herbs, rarely suffrutescent.

T. perfoliatum, Fever-Wort, has an erect hairy fistular round stem from one to four feet high. The leaves opposite, the pairs crossing each other, ovate, lanceolate, acuminate, entire, rather flat, abruptly narrowed into the petiole; the flowers sessile, apparently verticillate. It is a native of North America, in the United States, on rich rocky grounds, particularly in limestone soil.

The species of *Triosteum* will grow in almost any kind of soil, although they prefer a vegetable or peat mould, and they are easily propagated by dividing at the root or by seeds, which generally ripen in abundance.

TRIPHIANE. [SPIDUMENÆ.]

TRIPHA'SIA, a genus of Plants belonging to the natural order *Aurantiacæ*, of which the species are found in the East Indies, Cochinchina, and China. The calyx is 3-cleft; petals 3; stamens 6, rarely 5-8; filaments awl-shaped, flat; anthers cordate, oblong; fruit baccate, 1-3-celled; seeds 1 in each cell. The species form thorny shrubs with simple or trifoliate leaves. The fruit of *T. trifoliata* is acid in taste, something like the orange, and is both preserved and eaten as a fruit.

TRIPHYLENE. [IRON.]

TRIPOLI, a Mineral, occurring massive, with a coarse dull earthy fracture. It is meagre and rough to the touch, and yields readily to the nail. Colour, various shades of gray, yellow, and red. It imbibes water, which softens it; when burned it becomes white and is hardened; it is very difficult of fusion. It was first brought from Tripoli in Africa, but has since been found in France, Italy, and Germany. It is employed in polishing metals, marble, glass, &c. It consists of silica, alumina, and oxide of iron.

TRIPOXYLON. [CRABRONIDÆ.]

TRIPSURUS. [PICIDÆ.]

TRIPTOLEMÆA, a genus of Plants belonging to the natural order *Fabaceæ*, or *Leguminosæ*, and to the sub-order *Papilionaceæ*. The species are natives of warm climates, and yield the Rose-Wood of commerce.

TRISETUM, a genus of Plants belonging to the natural order *Graminaceæ*. The inflorescence is panicle; the spikelets 2-7-flowered; glumes with a keel, membranous; lower palea with 2 bristles, and a tender flexuose beard above the middle of its back; scale lanceolate.

T. flavescens, Golden Oat, or Yellow Oat-Grass, has the panicle much branched, spreading, erect; spikelets 3-flowered, all the florets awned. It is common in Great Britain, especially in rich pastures. Sheep are very fond of it.

TRISTICHIVS, a genus of Fossil Fishes from the Coal-Measures near Glasgow and Fernanagh. (Agassiz.)

TRITICUM, a genus of Plants yielding the various kinds of Wheat, and belonging to the natural order *Graminaceæ*. It derives its name, according to Varro, from 'tritum,' ground or rubbed, because the fruit in its preparation as a food for man undergoes the process of grinding or trituration. The various kinds of wheat have been known from a

very early period, and mention is made of wheat as a food in the earliest records of the history of man. Both the Egyptians and Jews made use of wheat as an article of diet, and this food is early mentioned in the Bible. It was also used by the Greeks and Romans, and Theophrastus and Pliny make frequent mention of it. On account of the early cultivation of many of the kinds of wheat as articles of diet, it is impossible to tell where the most common species are really indigenous. All the species of *Triticum* are however found most abundantly in temperate climates, and there take the place of the foods used in the hotter parts of the world. Wheat is in northern climates what rice and maize are in warmer ones. The part of the plant of *Triticum* which yields so large a proportion of the food of man is the fruit, seeds, or grain. This fruit, although small in itself, generally forms a large proportion of the plant. When the fruit is ground, the testa, or seed-coat, is separated from what is called the flour. This flour consists of the powdered albumen and embryo of the seed. The proximate vegetable principles which this flour contains are starch and gluten. The starch is a highly carbonised vegetable principle, whilst the gluten is characterised by possessing nitrogen. Foods that contain carbonaceous matters are fattening, whilst those that contain nitrogen are strengthening. It is thus that wheat-flour has become to be the staple article of diet of the finest races of men in the world. The other cereal grasses contain the same principles, but the gluten or azotised principle is not in so large a quantity as in wheat, as the following analysis of 100 parts of the organic matter of wheat, rice, and barley will show:—

	Starch.	Gluten.
Wheat	70.00	23.00
Rice	85.07	3.60
Barley	79.00	16.00

The starch is often separated from the gluten and used for various purposes in domestic economy. [STARCH.] Gluten is identical with fibrine, and is a form of Protein. [PROTEIN.]

The straw of wheat, and the chaff, or the culm, and the flowers, also contain 79 per cent. of organic matter. This consists principally of unazotised vegetable matter, and may therefore be used as an article of diet for cattle. The culms of wheat are also used for the purpose of making plait from which straw hats and bounnets are made, a manufacture of considerable importance in some parts of this country.

The genus *Triticum* is known by possessing solitary spikelets, with the glumes 2-valved and many-flowered; the valves carinate, acute, or mucronate; the paleæ 2-valved; the valves lanceolate, the external one acuminate, the internal one bifid at the extremity. The genus consists of about 40 species; of these 16 are European, and only 5 are natives of Britain. The species are divided into two groups—the *Cercalia*, yielding edible fruits; and the *Agropyra*, which are merely grasses. The latter group is by some writers, as Beauvois and Lindley, made into a distinct genus. It includes all the species that are natives of Great Britain.

The *Cercalia* are known by their spikelets being more or less ventricose and turgid, and the valves are ovate or oblong. These are again divided into the *Frumenta*, or True Wheats, in which the seeds fall out from the chaff; and the *Spelta*, or Spelts, in which the seeds remain attached to the chaff. The most important species belonging to the former division are the following:—

T. vulgare, Common Wheat, has a 4-cornered imbricated spike with 4-flowered spikelets, the valves ventricose, ovate, truncate, mucronate, compressed under the apex, the nerve somewhat prominent. This species includes the *T. aestivum* and *T. hybernium* of many botanists. They appear however to be only varieties of this species, differing in their periods of growth. The native country of this species is not well ascertained: it has been found wild in some districts of Persia, also of Siberia, apparently removed from the influence of cultivation. The *T. hybernium* is the Lammis, or Winter-Wheat, and embraces by far the greater number of varieties which are cultivated as the food of man. The wheats known in Great Britain and on the Continent as Fox, Kentish, Talavera, Bohemian or Velvet, Red, White, and Red-Eared Bearded Wheats, are varieties of *T. hybernium*.

T. turgidum, Turgid, Cone, or English Wheat, is known principally by its prominent carina. About 10 varieties of this species are known to agriculturists, half of which are summer and half winter wheats. Of these the Clock, Great or Revel Wheat, and the Russian, or Blue English Wheat, are the best.

T. durum, True Beard-Wheat, has the prominent carinae of the last wheat, with the valves ventricose, oblong, and three times longer than broad. It is a native of Switzerland. It has several varieties, all of which produce summer wheats, and are better known in Italy, Sicily, and Spain than in this country.

T. Polonicum, Polish Wheat, has the spike irregularly 4-cornered or compressed; the spikelets 3-flowered; the valves subventricose, oblongo-lanceolate, herbaceous, with many nerves. It is found native in some parts of Europe, not however in the country which gives it its name. In cultivation it yields summer wheats, which are adapted for warmer climates than Great Britain.

The Spelts include the following species:—*T. spelta*, Spelt-Wheat; *T. dicoccum*, Two-Grained, or Rice-Wheat; and *T. monococcum*, One-Grained Wheat.

The *Agropyra* do not possess ventricose-turgid spikelets, and the

valves are lanceolate or linear-oblong. This division includes the wheat-grasses, some of which are only known as troublesome weeds. The most remarkable instance of this is *T. repens*, Creeping Wheat-Grass, Couch-Grass, or Spear-Grass. The difficulty of getting rid of its creeping underground stem, the smallest portion of which if left in the ground sends up a fresh bud, is the cause of this plant being so great a pest to the farmer. The *T. maritimum*, a native of sea-coasts, seems to be only a variety of this plant.

T. junceum, Sea Rushy Wheat-Grass, *T. caninum*, Bearded Wheat-Grass, and *T. cristatum*, Crested Wheat-Grass, are other species of the *Agropyra*. [WHEAT, in ARTS AND SC. DIV.]

(Metzger, *Die Getreide-arten und Wiesengräser in Botanischer und Ökonomischer Hinsicht*, 1841; Koch, *Flora Germanica*; *Cyclopædia of Plants*; Sinclair, *Hortus Woburnensis*; Pouchet, *Traité de Botanique*; Babington, *Manual*.)

TRITON. [AMPHIBIA; SIPHONOSTOMATA.]

TRITONIA. [NUDIBRANCHIATA.]

TRITONIDEA (Swainson), a genus of *Mollusca*.

TRIURIDACEÆ, *Tailworts*, a small natural order of Plants belonging to Lindley's class *Dictyogens*. They have the dictyogenous structure, unisexual flowers, a free perianth, and numerous 1-seeded carpels. There are only two genera, *Triuris* and *Peltophyllum*. The species of these plants were discovered by Mr. Miers and Mr. Gardner in the woods of Brazil, where they delight in moist shady places. Their relations are with *Smilacaceæ*, *Menispermaceæ*, and *Trilliaceæ*. (Lindley, *Vegetable Kingdom*.)

TRIVIA. [CYPRIDEÆ.]

TRIXAGO, a genus of Plants belonging to the natural order *Scrophulariaceæ*. It has a tubular 4-cleft calyx, a tubular 2-lipped corolla, pointed capsules, and many-seeded cells. The seeds are slightly angular and very minutely crenate ribbed. *T. viscosa*, the only British species, has a round high simple stem, a fibrous root, and opposite leaves; the upper leaves are alternate, ovate, lanceolate, sessile, and acutely serrate. The flowers axillary, distant, and yellow; the anthers hairy. It is found in damp places in the west of Scotland and south of Ireland. (Babington, *Manual*.)

TROCHATELLA (Swainson), a sub-genus of *Mollusca* belonging to the family *Helicina*. [HELICIDÆ.]

TROCHELLA (Swainson), a sub-genus of *Calyptrea*, Lam., placed by him under the family *Heliotidae*. The shell is conical, patelliform; spire central, of two or more whorls; umbilicus closed.

T. auriculata Sow. ('Man.' f. 236); and *T. pileus* ('Man.' ff. 237-8), may be given as examples.

Professor Owen has contributed a most interesting addition to our knowledge of this genus, in his paper read before the Zoological Society of London, on the 8th November, 1842, on the anatomy of *Lithedaphus longirostris*, the synonyms of which he gives as "*Calyptrea Roissy*, Dufou (?) upper valve, *Calyptrea equestris*, auct. (?) *Mitralaria equestris*, Schumacher."

TROCHIDÆ, a family of Turbinate Gasteropodous *Mollusca*. The genus *Trochus* of Linnæus was placed by him between *Murex* and *Turbo*, in his last edition of the '*Systema Nature*,' and comprised 26 species.

The *Trochoidea* of Cuvier form the first family of his Pectinibranchiate Gastropods [PECTINIBRANCHIATA], and are defined by him as distinguishable by their shell, whose aperture is entire, without notch or canal for a mantle-siphon, the animals being destitute of one; and by an operculum or some organ in lieu of it. They are, Cuvier observes, the *Paracephalophora Dioica Asiphonobranchiata* of M. De Blainville.

M. De Blainville makes the *Goniostomata* his first family of the order *Asiphonobranchiata*, and includes within it the great genus *Trochus*, Linn., only. He describes the animal as spiral, having the sides of the body often ornamented with digitated or lobated appendages, and provided with a short foot rounded at its two extremities; the head furnished with two tentacles, more or less elongated, carrying the eyes on a convexity of their external base, which is often sufficiently distinct to render the eye subpedunculate; mouth without any upper tooth, with a lingual spiral riband; anus on the right, in the branchial cavity, which holds one or two unequal comb-like branchie; organs of generation terminating in a female individual on the right in the branchial cavity, and in a male individual in a sort of triangular tonguelet sustained by a small ossicle. Shell subplanorbic or trochiform; the spire elevated, sometimes depressed (*surbaisée*), and more or less carinated on its last whorl, which forms a flat circular base; a moderate, depressed, and often nearly quadrangular aperture, with its external or right lip trenchant, angular, or folded in the middle. Operculum horny, circular, with a submedian summit, rolled regularly into a spiral; the whorls of the spire narrow and numerous.

M. De Blainville observes that all the species of this family are phytiplagous, marine, and live upon the rocks on the shore of the sea. He divides the group into *Solarium* and *Trochus*.

Solarium.—Animal unknown. Shell orbicular, rolled up (*enroulée*) nearly on the same plane, or planorbic; spire very much lowered (*surbaisée*); a large conic umbilicus, with its edges denticulate or not at the entrance; aperture not modified by the last whorl of the spire, which is entirely flat; no columella. Operculum unknown (Blainville).

The number of recent species recorded by Woodward is 25, and of fossil 56.

The species of this genus hitherto found have occurred in the seas of the warmer climates. The Mediterranean, the Indian Ocean, the coasts of Tranquebar, the South Seas, and those of Australia are the localities recorded by Lamarck. The specimens have been found near the shore—it seems to be a littoral genus—on rocks and weeds.

S. perspectivum. Shell orbiculate-conoid, longitudinally-striated, whitish-yellow, with articulated belts of white and brown or chestnut near the sutures; the notches of the umbilicus small. (Lamarck.) Animal with a large foot widened in front, and having a very strongly developed marginal furrow, yellowish on the sides, marked with a black stria above. The head presenting a large escutcheon. The tentacles short, stout, and marked with two longitudinal black bands on the sides. At their base are placed the eyes on very short pedicles. The branchial cavity appeared to be partially divided in two, lengthwise, by a sort of fold. The intestine describes two rather considerable circumvolutions before it passes the liver. Operculum large, oval, membranous, and strongly but sparingly spiral at one of its extremities. The colour is yellowish, like that of the whole animal.

Messrs. Quoy and Gaimard, who have given this description of the animal in the '*Zoologie*' of the *Astrolabe*, state that they know nothing of the habits of this species, which was brought to them nearly dead by a Malay of Amboyna.

Solarium perspectivum.

a, front view; b, seen from below; c, operculum; d, anterior part of the animal. (Operculum and animal from the '*Atlas*' of the *Astrolabe*.)

S. variegatum.—Shell orbiculate-convex, transversely sulcated, longitudinally striated articulately, variegated with white and bay; umbilicus patulous and creuclated. (Lamarck.) Animal nearly of the same colour as the shell, which it secretes; for it is brown, dotted with black, on all parts. The tentacles are stout, long, obtuse, carrying the eyes at a certain distance from their base on a convexity. The foot is oval, rather large, widened, notched, and auriculated in front.

It carries at its posterior part one of the most singular of opercula, of an unique form among molluscs, and already known in collections by the account of M. de Roissy, but without the knowledge of the species to which it was to be referred. It is a long, solid, calcareo-membranous cone, carrying membranous lamellæ spirally throughout its length. The interspaces are as it were ribbed. (Quoy and Gaimard.) It is found at Carteret Harbour in New Ireland.

Shell of *Solarium variegatum*.a, the animal and shell of *Solarium variegatum*, together with the operculum, seen from below; b, the operculum. (Astrolabe.)

Trochus.—Animal well known, and as characterised above. Shell thick, ordinarily nacreous, trochoid, with the spire sometimes lowered (surbaissée), and at others rather lofty (élançée) and pointed at the summit; trenchant or carinated on its circumference, umbilicated or not; aperture depressed, angular or subangular, with disunited borders, the right lip trenchant; the columella bent, twisted, and often projecting in front.

Operculum horny, delicate, consisting of numerous narrow spiral whorls, increasing slightly from the centre to the circumference. (Blainv.)

The number of recent species of *Trochus* given by Woodward is 150, and fossil forms 360. The fossil forms are found in the Devonian rocks.

These plant eating marine gastropods are very widely diffused, there being few seas without some of the species: they have been captured at depths varying from the surface to 45 fathoms, creeping on rocks and sea-weeds, sand, sandy mud, and gravel.

T. obeliscus. Shell conico-pyramidal, nodulous and granulous, coloured with green and white; the whorls tuberculato-nodose, and girt with many granose circles; the last whorl, as it were, removed or taken away (dempto); the lower surface planulate; the lip sinuated at the base.

*Trochus obeliscus*.

a, anterior part of the animal, a portion of the operculum being visible at the lower part of the figure; b, operculum.

Animal with stout and short tentacles, which are white with a brown border; the ocular peduncles large, pointed, and doubly circled

with black. The muzzle is very wide, with a black riband near its border, as well as the head, which is moreover dotted with greenish. The foot is yellow below, and so dotted with brown on its sides that it appears black. The edge of the mantle is variegated with brown and greenish. The fringes of the feet are white and without filaments. (Quoy and Gaim.)

Lamarck gives the Indian Ocean as the habitat of his species. Messrs. Quoy and Gaimard, who captured the individual above described at Tonga, remark that in colour it is *T. obeliscus*, but that it tends to *T. acutus* in its suddenly-pointed spire.

The same zoologists observe that the opercula of *Trochi* known in collections are nearly all of a chestnut-colour. This, they remark, is ordinarily due to the action of the air, for on the living animal they are transparent and yellowish. In the very turriculated species the animal draws itself back into the shell obliquely, dragging in with it in this manner its operculum, which otherwise could not lie flat in the aperture, which is always more or less flattened. These animals, they add, show themselves but little, and hide themselves far in, so that none of their parts can be perceived. It is even necessary to break the first whorl of the shell in order to draw them satisfactorily. ('Astrolabe.')

T. imperialis. (Genus *Imperator*, Montf.) Shell orbiculate-conoid; the apex obtuse, violet-brown above, white below, with transverse imbricato-squamous furrows; the whorls turgidly convex, squamoso-radiate at the margin; the scales complicated; umbilicus infundibuliform. (Lam.)

Animal.—Foot oval, rather large; the muzzle elongated in form of a proboscis; the tentacles short, white, with a black or reddish line running lengthwise; ocular peduncles very stout, obtuse, the palmettes hardly visible. All these parts are whitish; the head and the mouth are striated across with black and violet: this last colour belongs only to the left side. The foot has some very bright marks on its sides; its lateral fringes are without filaments.

Operculum oval, smooth, whitish, and a little convex (renflé) towards one of its extremities. ('Astrolabe.')

Messrs. Quoy and Gaimard, who observe that the operculum of this species determined them to place it in the genus *Turbo*, state that it has only been hitherto found at New Zealand, where it is rare. They never obtained more than one living specimen. That from which the description and figure were taken was small, being only two inches in diameter, comprising the spines. It was covered with calcareous incrustations and marine plants, indicating the sloth of the animal. They found it in the Passe-des-Français, Tasman Bay.

*Trochus imperialis*, with animal.

a, anterior part of the animal seen from above; b, inside of operculum; c, outside of the same.

Dr. J. E. Gray makes the *Trochidae* the second family of his *Podophthalma*, the first section of the order *Phytophaga* in his

arrangement. The *Trochide* are immediately preceded by the *Turbinide* and followed by the *Stomatellide*.

Dr. Gray's *Trochide* consist of the genera *Pyramis*, *Cardinalia*, *Trochus*, *Polydonta*, *Clangulus*, *Phorcus* (Phorus?), *Ziziphinus*, *Canthiridus* (*Cantharidus*?), *Thalotia*, *Monodonta*, *Gibbium*, *Gibbula*, *Rotella*, *Livona*, *Talopia*, *Camitia*, and *Delphinula*. ('Synopsis Brit. Mus., 1840.)

In Woodward's 'Manual,' *Solarium* is referred to *Chilonide*, and *Trochus* to *Turbinide*.

TROCHIDON. [TROCHIDÆ]

TROCHILIDÆ, the scientific name for the family of Humming-Birds.

Linnæus, in his last edition of the 'Systema Naturæ,' placed the genus *Trochilus* at the end of his order *Picæ*, and next to the genus *Certhia*.

Cuvier includes the *Colibris* (*Trochilus*, Linn.) in his order *Passe-reaux*, placing the group between the *Grimpereaux*, or *Creeper*s (*Certhia*, Linn.), which in Cuvier's arrangement comprises the *Sun-Birds* and the *Hoopes* (*Upupa*, Linn.). [CINNYRIDÆ]

M. Lesson, in his 'Manuel,' places the *Trochilide* next to the *Philedonide*, and at the end of the *Tenuirostres*, making the family consist of two genera only, namely, *Colibri* (*Polytmus*, Brisson; *Trochilus*, Linn. and Auct.), and *Ornismya*, Less. (*Mellisuga*, Brisson; *Trochilus*, Linn., Temminck, Vieillot; and *Orthorhynchus*, Lacép.). The same zoologist, in his elegantly illustrated work 'Les Trochilidées, ou les Colibris et les Oiseaux Mouches,' gives the following definition of this brilliant group:—

Trochilus (auctorum).

Synonyms:—*Mellisuga* and *Polytmus*, Brisson; *Trochilus*, Linn., Gmelin, Latham, Vieillot, Temminck; *Trochilus* and *Orthorhynchus*, Lacép.; *Trochilus*, *Cyanthus*, *Phæthornis*, *Campylopterus*, and *Lampornis*, Sw. ('Zool. Journ.'). *Trochilus*, *Ramphodon*, and *Ornismya*, Less.; *Bellatrix*, *Calliphlox*, *Polytmus*, *Glaucis*, *Anthracothonax*, *Heliactin*, *Hylocharis*, *Basilinna*, *Chrysolampis*, *Smaragdites*, and *Eulampis*, Boie ('Isis,' 1831).

Zoological Characters.—Bill longer than the head, straight or arched, the upper mandible a little widened at the base, rounded above and beyond the nostrils, tapering into a point; lower mandible straight or slightly bent above and below, entering within the upper mandible, dilating a little towards the point, and of the same length as the preceding. Nostrils basal, very small, covered by the advanced feathers of the forehead, placed in a lateral fossa, separated from each other by a slight ridge. Wings with the quill-feathers graduated; the first the longest, and so on in succession. Tail composed of ten feathers, very variable in length and form. Tarsi delicate, slender, naked or feathered to the heels, scutellated, having in front three equal toes, the two internal ones a little connected at their base, the hind toe rather stout, all furnished with compressed, curved, and hooked claws, which are rather robust for the toes. Tongue extensible, long, divided at the summit into two widened filaments, which are slightly spatulate, and supported by two very long branches of the os hyoides acting like a spring, tubular in the centre, or formed of two co-adapted (adossés) cartilaginous canals.

Geographical Distribution.—America (including many of the adjoining islands), principally between the tropics; but, at the same time, there are species which range very far to the south, and others to the north.

Food.—Soft insects, such as spiders, tipulæ, gnats, ants, and also small coleopterous insects; accessorially the honeyed juice of flowers.

Plumage.—That of the male brilliant, sumptuous, and with metallic reflections. The livery of the females is nearly always sombre, tarnished, or with but little brilliancy. The young resemble the females, and only gradually gain the dress of the males. The feathers have their barbs constantly disposed in facets, even in those whose plumage is dull.

In the 'Synopsis' of his 'Classification of Birds' Mr. Swainson gives the following arrangement and definitions, observing that the typical characters alone are given of what he considers to be the primary groups; but as the circular succession of the sub-genera in each is a subject which requires more investigation than he had been able to give it, he will not attempt to impose names upon the minor groups, which could not as yet be properly demonstrated.

Family *Trochilide*. Humming-Birds.

Wings excessively long, falcated. Feet very small.

Genera:—*Lampornis*, Sw.; Ex. *L. mango*. *Trochilus*, Auct.; Ex. *T. longirostris*. *Cyanthus*, Sw.; Ex. *C. forficatus*. *Phæthornis*, Sw.; Ex. *P. superciliosus*. *Campylopterus*, Sw.; Ex. *C. recurvirostris*.

He places the *Trochilide* between the *Cinnyridæ* and the *Promeropideæ*.

Prince C. L. Bonaparte, in his 'Specchio Comparativo' (1827), places the family *Anthomyzi*, with the genus *Trochilus*, between the families *Tenuirostres* and *Myiophali*. In his 'Birds of Europe and North America' (1833) the *Trochilide* are arranged between the *Upupideæ* and the *Certhideæ*, and comprise the genera *Trochilus*, *Lampornis*, and *Calliphlox*.

Mr. G. R. Gray, in his 'List of the Genera of Birds,' gives the

Trochilide a place between the *Nectarinide* and the *Meliphagide*, making the first-named family consist of the following sub-families and genera:—

Sub-Family 1. *Lampornine*.

Genera:—*Campylopterus*, Sw.; *Eulampis*, Boie; *Petasophora*, G. R. Gray; *Lampornis*, Sw.; *Glaucis*, Boie; —(?) (*Chrysures*, Less.); *Topaza*, G. R. Gray; *Calothorax*, G. R. Gray (*Lucifers*, Less.).

Sub-Family 2. *Phæthornine*.

Genera:—*Grypus*, Spix; *Phæthornis*, Sw.

Sub-Family 3. *Trochiline*.

Genera:—*Patagona*, G. R. Gray (*Patagones*, Less.); *Cæligena*, Less.; —(?) (*Glaucopes*, Less.); *Lesbia*, Less.; *Heliactin*, Boie; *Trochilus*, Linn.; *Heliothryx*, Boie; —(?) (*Platurus*, Less.); —(?) (*Avocettes*, Less.); *Polytmus*, Brisson; *Amisilis*, Less.; *Sephanoides*, Less.; *Orthorhynchus*, Cuv.; *Mellisuga*, Brisson; *Chrysolampis*, Boie; *Hylocharis*, Boie; *Lophornis*, Less. (*Bellatrix*, Boie; *Coquets*, Less.).

The most recent work on this subject is by Mr. Gould, who is now (1855) bringing out a work on the *Trochilide*, in which every species will be figured. Mr. Gould has long been preparing for this great work, and has one of the finest collections of Humming-Birds ever made. The collection of the late Mr. George Loddiges, which in 1842 was the most extensive in Europe, contained 196 species. In Mr. Gould's collection there are above 300 species. This collection was publicly exhibited in the Gardens of the Zoological Society in Regent's Park, in 1851 and 1852. The monograph of the *Trochilide* which is to illustrate this great collection has already reached ten parts, and will be completed in sixteen.

The following is a list of the genera, as given by Mr. Gould:—

Grypus, Spix.—Ex. *Trochilus naevius*, Dumont. It is the only species of this genus, and inhabits the mountainous districts of Brazil.

Glaucis, Boie.—Ex. *T. aquila*, Bourcier. It inhabits New Granada. *Phæthornis*.—Ex. *T. hispidus*, Gould. It is an inhabitant of Peru. There are several species.

Lafresnaya, Bonaparte.—Ex. *T. Lafresnayi*, Bois. There is another species, both inhabitants of Quito.

Doryfera, Gould.—Ex. *T. Ludovica*. Several species are natives of Peru.

Petasophora, G. R. Gray.—This is a genus remarkable for its beauty. The oldest known species constitutes the type, the *P. Scirirostris*. There are eight species, natives of Brazil.

Heliothryx, Boie.—The species of this genus are eminently adapted for flight. The type of the genus is *T. auritus*.

No other species are in Mr. Gould's collection. They are natives of Brazil and Guyana.

Bellatrix, Bonaparte.—This genus contains four species. Ex. *T. fulgens* of Swainson, a native of Mexico.

Heliodoxa, Gould.—Ex. *H. Iacula*, Gould. It inhabits Santa Fé de Bogotá.

Heliomaster.—Ex. *T. longirostris*, Vieillot. The species are natives of the Antilles and of Brazil.

Mr. Gould separates from the foregoing genus a species to which he gives the generic title of *Pterophorus*. It is a native of the mountain range of Columbia, and ranks amongst the most gorgeous of the *Trochilide*.

Campylopterus, Swainson.—Ex. *C. latipennis*, the Blue-Throated Sabre-Wing. Nine species are known, natives of the borders of the Amazon.

Lampornis.—Ex. *T. Mango*. It inhabits Jamaica. There are several species.

Eulampis, Boie.—Ex. *T. holosericus*. This species, according to Lesson, is confined to the Antilles.

Polytmus, Bonaparte.—This genus contains but one species, *T. polytmus* of Jamaica.

Topaza, Gray.—Ex. *T. Pella*, the Topaz-Throated Humming-Bird; a native of Rio Negro, Brazil.

Cæligena.—Ex. *T. cæligena*, the Purple Humming-Bird. A second species of this genus has been received by Mr. Gould from Bolivia.

Leucippus, Bonaparte.—No species are recognised by Mr. Gould natives of Venezuela.

Bourcieria, Bonaparte.—There are four species, of which *T. Wilsoni* is an example.

Agleactis, Gould.—Ex. *T. cupreipennis*; a native of Columbia.

Florisuga, Bonaparte.—The type of this genus is *T. mellivorus* of Linnaeus; a native of Cayenne, Surinam, and the Antilles. Two other species are known.

Hylocharis, Boie.—Of this genus, the Sapphire-Throated Humming-Bird, *T. sapphirinus*, and the Golden-Green Humming-Bird, *Ornismya prasina*, are examples. It is a native of Guyana, Cayenne, Brazil, and Berbice.

Docimaster, Gould.—This genus contains but one species, *T. ensiferus*.

Helianthea, Gould.—The types of this genus are *T. helianthea* and *T. Bonapartei*, natives of New Granada and Venezuela.

Patagona, Gray, contains only one species, *T. gigas*; a native of Chili.

Mallura, Gould.—Five species belong to this genus. They are natives of Bolivia.

Aracetinus, Bonaparte, contains two species.—Ex. *T. Aracetta*.
Chrysauronia, Bonaparte.—Four species are arranged under this genus. They are natives of Brazil and Peru. Ex. *T. Anone*.
Heliangelus, Gould.—This is a gorgeous group. All the species are natives of the Andes. Six species are recorded.
Oreotrochilus.—Six species are recorded from South America. Ex. *T. Chimborazo*.
Thalurania, Gould.—The type of this genus is the Fork-Tailed Humming-Bird, *Ornismya furcata* of Lesson.
Saucerottia, Bonaparte.—Ex. *T. Saucerotti*. The species are natives of New Granada.
Amazilius, Bonaparte.—Ex. *Ornismya Amazilii* of Lesson. It is a native of Peru.
Thaumatius, Bonaparte.—Ex. *Trochilus Thaumatius*. Natives of Brazil.
Ramphomieron, Bonaparte.—Eight or nine species of this group are described. The type of the genus is *T. microrhynchus*, a native of Santa Fé de Bogotá.
Oxygogon, Gould.—The types of this genus, which contain but very few species, are the *Ornismya Guerini* and *O. Lindeni*.
Loddigesia, Gould.—One species of this genus is recorded, *T. mirabilis*; a native of Peru.
Spathura, Gould.—Ex. *Ornismya Underwoodii*, the Rough-Legged Racket-Tailed Humming-Bird. Natives of Peru.
Eriopus, Gould.—The species are natives of the Cordilleras, Peru, and Columbia. There are fourteen or sixteen species recorded.
Cynanthus.—Ex. *T. Nuna*, the Nuna Humming-Bird; a native of Peru.
Conetes, Gould.—This genus contains only two species, of supreme magnificence. Ex. *T. sparganurus*, the Sappho.
Trochilus, Linnaeus and Bonaparte.—Mr. Gould gives to this genus the title of *Colibri*. The typical example is the Ruby-Throat, or Northern Humming-Bird, *T. Colubris*.
Ornismya, Bonaparte.—There are several species natives of Jamaica.
Selasphorus, Swainson.—Ex. *T. ruber*, the Nootka Sound Humming-Bird.
Sephanoides, Lesson.—Ex. *T. Galerita*. Valparaiso.
Chrysolampis, Boie.—This genus is represented by the Ruby-Crested Humming-Bird, *T. moschitus*. It is a native of the Antilles, and probably also of Guyana.
Orthorhynchus, Cuvier.—Ex. *T. chlorolophus*, a native of Martinique.
Cephalipis, Loddiges.—Ex. *T. Loddigesii*, Gould. It is a native of Rio Grande.
Lophornis, Lesson.—There are several species. Ex. *T. auratus*; a native of Guyana, Cayenne, and Brazil.
Discosura, Bonaparte.—Ex. *T. longicaudatus*; a native of Guyana.
Tryphæna, Gould.—The type of this genus is *Tryphæna Duponti*, a native of Mexico. There are four species described.
Augastes, Gould.—Ex. *T. superbus* (Vieill.); a native of Brazil. There are two species described.
Calothorax, Gray.—The type of the genus is *Trochilus lucifer*, Swainson.
Heliactin, Boie.—One species is only recorded, *T. cornutus*; a native of Brazil.
Thaumastura, Bonaparte.—The type of this genus is *Trochilus Cora*, Lesson; a native of Peru.
Gouldia, Bonaparte.—The example of this genus is *T. Langedorfi* of Vieillot, a native of Brazil. There are two or three species described.

The birds belonging to this family are no less remarkable for their structure than for the wonderful splendour of their plumage. The very deep keel of the sternum, the power of the bones of the wing, lengthened scapula, and the comparatively impoverished structure of the lower extremities, all exhibit an organisation of the locomotive system especially adapted to the development of the highest powers of flight.

Skeleton of Humming-Bird. (From a specimen in the Museum of the Royal College of Surgeons in London.)

To put this framework in motion a corresponding development of the muscular system is applied. The enormous—for enormous, by comparison, they are—pectoral muscles, and the other muscles employed for working the wings, form nearly the whole fleshy substance of the bird: those allotted to the feet are reduced to the least possible quan-

tity consistently with the requisite stability. All proclaims that the being before us is destined to pass the most active part of a highly active life in the air; and when we proceed to inquire into the habits of this ethereal race, we shall at once perceive how admirably adapted to those habits this organisation is.

Another part of the mechanism of these minute creatures, intimately connected as it is with their existence, demands some notice. The tongue is the principal organ for obtaining the food, which consists of the honied juices of flowers and insects. This tongue is so framed that, like the same organ in the Woodpeckers, it can be darted out of the bill by a sudden action of the os hyoides, comparable to that of a spring suddenly released from the detent. It is very long, and can be protruded a good way from the bill.

In order that this tubular tongue may be thus projected upon the aliments which its terminations are appointed to seize and retain, the os hyoides which supports it is formed of two bony plates which separate, pass below the cranium, re-ascend over the bones of the occiput, and proceed to form a point of resistance, or fulcrum, by their re-union on the forehead. The result of this disposition, when brought into play by the muscles of the tongue, is a great power over the muscular tubes, furnished with circular fibres, which compose the organ of taste. The two small blades, or elongated spoon-like terminations, seize the insects, or lick up the honied exudations, which are on the instant carried to the aperture of the oesophagus by the elasticity and contractility of the two tubes, and forthwith swallowed. The long and slender bill comes admirably in aid to insert the tongue into the nectaria of flowers.

Bill and Tongue of Humming-Bird.

a, the head, profile; the tongue protruded from the bill, and showing its bifurcation; the two branches of the os hyoides are seen surrounding the cranium; b, the same seen from above, the two branches of the os hyoides uniting at a pointed angle in front; c, the same seen from below; d, the tongue much magnified, with some of its soft parts dissected away, but adhering to the os hyoides and its branches, as well as to the larynx, seen from above; e, the same seen from below, with the os hyoides only, and the two lamellæ of its point separated; f, portion of the tongue very much magnified, seen from above, so as to convey the idea of the manner in which the cylinders that form it are united; g, the lower side of the same. (Lesson.)

The sight of the Humming-Birds is well developed, and very acute within the range required ordinarily for its exercise: the sense of hearing is quick.

The plumage in which these dazzling birds are clad defies description either with pen or pencil. The most brilliant metallic tints, the hues of the richest gems, fade before the display made by many of the living adult males. "Splendet ut sol," says Macgrange, speaking of one of them. Audubert applied himself to account for this brilliancy of colour, and to demonstrate on mathematical principles that it is due to the organisation of the feathers, and to the manner in which the luminous rays are reflected on falling upon them. M. Lesson thinks that this colour is, first, the result of the elements contained in the blood and elaborated by the circulation; and that, secondly, the

texture of the plumes plays the principal part in consequence of the manner in which the rays of light traverse them, or are reflected by the innumerable facets which a prodigious quantity of barbles or fibres present. As an example of the diversity of tints which spring from such scaly feathers, M. Lesson cites the emerald 'cravat' of many species, which takes all the hues of green, and then the brightest and most uniformly golden tints down to intense velvet black; or that of ruby, which darts forth pencils of light, or passes from reddish-orange to a crimsoned red-black.

The females generally speaking are without the splendour of the males; and are clad in modest, not to say sombre, plumage. The same may be said of the young males till the second year, when traces of the future brilliancy begin to appear here and there; but on the third year all remains of the sober livery of youth have vanished, and the bird shines out in the full radiance of his nuptial dress.

The small feet are generally of a dark colour: several species, especially those which live high up in the mountainous regions, have the tarsi warmly and largely protected with white plumelets, so that the birds look as if they had downy muffs on their legs.

The native names of the Humming-Birds were, as might be expected, first made known by the Spaniards and others who first invaded the New World. With the ancient Mexicans these bright creatures appear to have been great favourites. The radiant mantles worn by the natives in Montezuma's time glittered with the spoils of these diminutive birds, which were also employed in the art of design, and in the composition of those embroidered pictures which Cortes has so highly praised. Humboldt notices the religious belief of the Mexicans that Toyamiqui, the spouse of the God of War, conducted the souls of those warriors who had died in defence of the gods into the mansion of the sun, and transformed them into humming-birds; and it must be owned that they form an emblem of the soul hardly less spiritual than the butterfly of the Greeks. Hernandez treats of the Mexican species under the names of *Hoitzitziltototl*, or *Arvis varia*; and in the 'Nova Plantarum, Animalium, et Mineralium Mexicanaorum Historia à Francisco Hernandez Medico in Indiis præstantissimo primum compilata, dein à Nardo Antonio Reccho in Volumen digesta,' &c. (Romæ, 1651, folio), we find seven species figured under the general title of *Hoitzitzil*, and the specific designations of *Xiu Hoitzitzilin*, *Etsal Hoitzitzilin*, *Ystac Hoitzitzilin*, *Tenoc Hoitzitzilin*, *Quetsal Hoitzitzilin*, *Tozcacoz Hoitzitzilin*, and *Xoe Hoitzitzilin*. Ximenes writes the word *Hoitzitzil*. Gomara gives *Vicieilin* as the name. John de Lact writes *Quenti* as the Peruvian and *Tomineios* as the Spanish appellation. Ourissia is the name recorded by Nieremberg; and Guianumbi, according to Margrave and others, is the Brazilian designation. These and other Indian terms are said to signify 'rays of the sun,' 'tresses of the day-star,' 'murmuring birds,' and the like. The Spanish *Tomineos*, or *Tomineios*, seems to refer to their diminutive size and small weight;* and *Picaflores*, another term employed by the Spanish or Portuguese creoles, to their mode of taking their food. Captain Lyon, R.N., in his 'Journal of a Residence and Tour in the Republic of Mexico' (1828), states that in the neighbourhood of Xalapa the Humming-Bird is distinguished by the names of *Chupa-Rosa* and *Chupa-Myrta*, *Rose-Sucker* and *Myrtle-Sucker*.

It is not to be wondered at that fable should have its share in accounting for the origin and describing the habits of these diminutive aerial beings. Thus, while the more sober believed that they were hatched from eggs like other birds, others fancied that they were transformed from flies, some going so far as to declare that they had been seen in the half-fly half-bird state. Then again they were supposed to live no longer than the flowers which afforded them food, and when those flowers faded they were believed to fix themselves by the bill to some pine or other tree, and there remain during the dreary months till the descending rains brought back the spring, when they revived again, to undergo the same alternation of life and death. Gomara states that they expired in the month of October, having previously suspended themselves by their feet from a branch in some warm place, and were renaescent in April.

Humming-Birds were in the museum of the Tradescants under that name, this name having been given them on account of the noise they make with their wings whilst flying. In the 'Museum Tradescantianum,' by John Tradescant (12mo., London, 1656), we find in the catalogue of 'Whole Birds,' "divers Humming-Birds, three sorts whereof are from Virginia."

Mr. Darwin states that two species are common in Chili, and that he has seen a third within the Cordilleras at an elevation of about 10,000 feet. He adds that in the wooded island of Chiloe, which has an extremely humid climate, *Mellisuga Kingii*, skipping from side to side amidst the dripping foliage, is perhaps more abundant than any other kind. It there very commonly frequents open marshy ground, where a kind of bromelia grows: hovering near the edge of the thick beds, it every now and then dashed in close to the ground; but Mr. Darwin could not see whether it ever actually alighted. At the time of year referred to by him there were very few flowers, and none whatever near the beds of bromelia. Hence he was quite sure they did not live on honey; and on opening the stomach and upper intestine, by the aid of a lens he could plainly distinguish, in a yellow

* *Tomlin*, the third part of a drachm, Spanish tray weight.

fluid, morsels of the wings of *Diptera*, probably *Tipulida*. It is evident, he observes, that these birds search for minute insects in their winter-quarters under the thick foliage. He opened the stomachs of several specimens, which were shot in different parts of the continent; and in all remains of insects were so numerous as often to present a black comminuted mass, as in the stomach of a creeper. Mr. Darwin goes on to state that in Central Chili these birds are migratory, making their appearance there in autumn, and that in the latter end of the month corresponding to our October they were very common. They began to disappear in the spring, and on the 12th of what would correspond to our March he saw, in the course of a long walk, only one individual. As this species migrates to the southward, it is replaced by the arrival of the larger kind presently to be noticed. Mr. Darwin does not believe that the small kind breeds in Chili, for during the summer their nests were common to the south of that country.

Numbers of the large species (*Trochilus gigas*) arrived in the neighbourhood of Valparaiso, during the year in question, a little before the vernal equinox. Mr. Darwin describes it as coming from the parched deserts of the north, probably for the purpose of breeding in Chili, and says that when on the wing its appearance is singular. He observes that, like others of the genus, it moves from place to place with a rapidity which may be compared to that of *Syrphus* among *Diptera* and *Sphinx* among moths; but, whilst hovering over a flower, it flaps its wings with a very slow and powerful movement, totally different from that vibratory one common to most of the species which produces the humming noise. He declares that he never saw any other bird where the force of its wings appeared (as in a butterfly) so powerful in proportion to the weight of its body. He tells us that when hovering by a flower, its tail is constantly expanded and shut like a fan, the body being kept in a nearly vertical position. This action, he says, appears to steady and support the bird between the slow movements of its wings. He further states that, although flying from flower to flower in search of food, its stomach generally contained abundant remains of insects, which he suspects are much more the objects of its search than honey; and that its note, like that of nearly the whole family, is extremely shrill.

The nests of these birds are as wonderful as any that are made. They vary greatly in form and structure; but in all the soft and delicate materials are so put together as to furnish as much warmth

Nest of Humming-Bird. (Lesson.)

Nest of Humming-Bird, with eggs. (Lesson.)

as possible, an object of first-rate importance where the body of the parent, generally speaking, is so small, and the quantity of animal heat given out must be in proportion.

Prince Maximilian de Wied, on examining the flower of a palm-tree in Brazil, found affixed to it the nest of the Blue-Headed Humming-Bird (*Trochilus pileatus*, *Ornismya cristata*, Less.), which, he says, much resembles that of the *Trochilus bicolor* of authors. He found it as well covered with moss as those of the Goldfinch and many other small European birds. The Prince adds, that in all humming-birds' nests two white eggs of an elongated form are found, which in some species are extraordinarily small. This rule as to the duality of the eggs is not without exception, if the information given to Sir William Jardine be correct, that the Doctor Humming-Bird, as it is provincially termed (*Trochilus hirsutus*), builds its nest suspended like that of the Yellow-Tail (*Cusacus cristatus*) with the entrance somewhat downwards, and lays only one egg. This nest is described as being of a lengthened form, composed of dried grass and slender roots, moss, &c., as not of the general compact structure, and as suspended from the leaf of some reed-like plant, to which it is cemented chiefly by the threads of spiders or caterpillars.

Nest of the Brazilian Amethyst Humming-Bird (*Ornismya amethystoides*, Less.),
a, the egg.

Cotton, thistle-down, delicate fibres, a fungus-like substance, and other soft materials woven into a compact and fleecy substance, enter into the composition of the nests of Humming-Birds. The outside is in most instances covered with lichens, generally supposed to be stuck on with a sort of glue secreted by the bird; but we have reason to believe that this is not so. The nest generally appears to be made by warping spiders' webs over fragments of plants, their down, lichens, &c.; and the lichens, which are never turned the wrong way, are secured by the webs only.

Captain Lyon gives an account of a Humming-Bird which built its nest in an orange-tree. The young were hatched at first in a shallow nest, but as the young increased in size, the mother built her nest higher, so that from having at first the form of figure 1, it became ultimately like figure 2,

The parents are most valiant in defence of their nests. Oviedo relates how they will fly even at the face of a man who climbs a tree where their nests are, and strike him in the eyes, coming, going, and returning so swiftly, that no man would well believe it who had not seen it. Mr. Bullock says that the female of the Mexican Star lays two eggs, perfectly white, and large for the size of the bird; and the

Indians informed him that they were hatched in three weeks by the male and female sitting alternately. He states that when attending their young, they attack any bird indiscriminately that approaches the nest. This pugnacious audacity probably fostered the Mexican belief that these diminutive bodies contained the souls of slain warriors.

Medical virtues have been attributed to these bright beings. Powdered Humming-Bird was considered a specific in cases of epilepsy; and the alleged efficacy of the birds in curing rheumatism secured a place for them in the old European Pharmacopœia.

We proceed to give a very few examples of the multitudinous forms presented by this gorgeous race.

Sickle-Winged Humming-Bird, *Trochilus falcatus* Sw. Green; throat and breast shining-blue; body and vent blue-green; tail even, rufous cinnamon; exterior quills falcated, the shafts dilated and compressed. It is a native of the Spanish Main.

Sickle-Winged Humming-Bird (*Trochilus falcatus*, Sw.), a little reduced.

Recurved-Bill Humming-Bird, *Trochilus recurvirostris*, Sw. Golden-green; throat shining emerald-green; middle of the breast and body black; lateral tail-feathers beneath topazine; bill recurved. (Sw.) It is a native of Peru.

Recurved-Bill Humming-Bird (*Trochilus recurvirostris*, Sw.).

Gould's Humming-Bird, *Ornismya Gouldii*, Lesson.—This bird, *Ornismya ornata*, and the Hausse Col Blanc (*O. strumaria*, Less.), form a small natural tribe. The Huppe Col (*O. ornata*), which is figured by M. Lesson (pl. xli., male and female, Oiseaux Mouches, very young, pl. xxiv., Trochilidées), is found in Guyana, Brazil, and Trinidad; the Hausse Col, figured by M. Lesson (pl. xliii., male; pl. xliiii., female and young, Oiseaux Mouches), is found in Brazil.

Gould's Humming-Bird (*Ornismya Gouldii*, Less.)

The Bar-Tailed Humming-Bird, Sappho Humming-Bird of Lessou. This is the *Trochilus sparganurus*, or Bar-Tailed Humming-Bird of Shaw; *Ornismya Sappho*, Less.; *T. radiosus*, Temm. (Galleries of the Museum); *T. chrysurus*, Cuv.; *T. chrysocloris*, Vieill.)

It is a native of the east of Peru.

Bar-Tailed Humming-Bird (*Trochilus sparganurus*). (Lesson).

The Double-Crested Humming-Bird, *Trochilus cornutus*, Wied.; *Trochilus bilophus*, Temm.; *Ornismya chrysolopha*, Less.

Male.—Bill and feet very weak and obscure in colour. Two flattened fan-shaped crests, each composed of six small feathers, part from the forehead on a level with the eyes. The brilliancy of these crests surpasses description, glistening as they do with the hues of polished gold and red copper, changing into the gemmy tints of the ruby and emerald, now fire-coloured, anon the purest green, and presently the brightest yellow. The scaly feathers of the forehead between the two crests sparkle with metallic uniform green, changing to steel or sapphire blue. A camail of dark changeable violet extends from the throat behind the eyes, and descends along the sides of the neck to terminate in a point of long feathers before the breast. This uncertain violet graduating into a non-metallic blue, with its velvety very dark tint, is sharply defined on the milk-white of the breast, which extends to the lower part of the neck, so as to form a rather large white collar. The lower part of the belly is white; but the middle of the abdomen and the flanks are, like the back, golden-green, with which is mingled a little of the grayish colour of the base of the feathers.

Back and sides of the head behind, back, and feathers of the rump, metallic golden-green. Quills brown. Tail graduated, composed of four feathers longer than the six others; the two middle ones are brown, the two external pure white. The other shorter external tail-feathers are white, but their outer border is variegated with brown. The tail below is white, slightly smoked as it were. The wings reach only to the half of the tail, the general form of which is long, acuminate, and narrow. Length 4 inches 5 or 6 lines. Bill $6\frac{1}{2}$ lines.

Double-Crested Humming-Bird (*Trochilus cornutus*, Wied), adult male.

The Cora Humming-Bird, *Ornismya Cora*, Less. Upper part of the head, back, rump, and coverts of the wings, uniform and metallic

Cora Humming-Bird (*Ornismya Cora*, Less.).

green. A wide iridescent gorget occupies the throat down to the half of the neck and to the cheeks; the lower part of the neck in

front, the breast, and all the lower parts of the body, are tarnished white, with a little brown on the flanks. Tail, consisting of eight brownish feathers, bordered with white within; two middle feathers much longer than the others, white on their internal side, brownish on their external border, and entirely brown at the extremity. Bill slender, black. Feet reddish. Total length 5 inches 5 lines (French); of this the tail measures 3 inches 2 lines, and the bill 6 lines. It is a native of Peru, and especially the Plain of Lima.

All the species of Humming-Birds are exclusively natives of the New World where they are found, from one extremity of the continent to another. One species is described as inhabiting America as far north as Sitka, whilst another has been found at Cape Horn. One group, the genus *Oreotrochilus*, is found at the height of 15,000 feet above the level of the sea, where they feed upon the *Coleoptera* and *Hymenoptera*, which frequent the alpine plants of these snowy regions. They abound however in the tropical regions of America, and are most numerous in the deltas and along the banks of the great rivers which flow through this vast continent.

Some species are found in the West Indian Islands which are not found on the continent. One island in the Pacific teems with these birds, and three species are found peculiar to the island of Juan Fernandez.

Many attempts have been made to bring these beautiful birds to Europe, but with one exception they have all failed. It has not been found difficult to keep them for a short period in captivity in their native countries, but no permanent success has attended the oft-repeated experiment of bringing them to the Old World.

TROCHILUS. [TROCHILIDÆ.]

TROCHOIDEA. [TROCHIDÆ.]

TROCHOIDEUS. [PAUSSIDÆ.]

TROCHUS. [TROCHIDÆ.]

TROGLODYTES. [CHIMPANZEE; TROGLODYTINÆ.]

TROGLODYTINÆ, a family of Insectorial Birds, to which the Wrens belong.

Linnaeus placed the true Wrens among his *Motacilla*.

Meyer arranged them in the third sub-order, *Subulata*, of his fifth order, *Oscines*.

Cuvier gave them a place under his *Bec-Fins* (*Motacilla*, Linn.), with the generic names of *Regulus*, Cuv., and *Troglodytes*, Cuv.

M. Latreille makes them members of the second family, *Dentirostres*, of his second order *Passereaux*.

The position assigned to the sub-family *Troglodytinæ*, or Wrens, by Mr. Swainson, is between the *Sittinæ* (Nuthatches) and the *Buphaginæ* (Oxpecker), in the family *Certhiada*.

The following is his character of the *Troglodytinæ*:—Feet with the tarsus longer than the hind toe, which is but slightly developed; lateral toes nearly equal, and cleft to their base; the tenuirostral division.

The genera which Mr. Swainson arranges under this sub-family are—*Platyrus*, Sw.; *Thriothurus*, Vieill.; *Troglodytes*, Linn.; *Lochmia*, Sw.; *Tichodroma*, Ill.

Mr. Swainson arranges the Golden-Crested Wrens, or Gold-Crests, as he terms them, among the *Sylviada*.

Prince Bonaparte, in his 'Birds of Europe and North America,' places the genus *Troglodytes*, of which he records one European and three American species, next to the genus *Certhia*, in his sub-family *Certhiina*; and he makes *Regulus*, of which he notices three European and three American species, the first genus of his sub-family *Parina*. *Regulus*, in the Prince's arrangement, is immediately followed by *Parus*.

The *Troglodytinæ* of Mr. G. R. Gray form the seventh and last sub-family of his family *Certhiada*, and comprise the following genera:—*Rhinocrypta*, G. R. Gray; *Menura*, Dav.; *Pteroptochos*, Kittl.; *Seylaopus*, Gould; *Microua*, Gould; *Merulaxis*, Less.; *Thriothurus*, Vieill.; *Campylorhynchus*, Spix; *Rhamphocenus*, Vieill., and *Troglodytes*, Cuv.

The genera *Troglodytes* and *Regulus* are examples of this group.

Troglodytes Europæus, *Motacilla troglodytes*, Linn., is the Troglodyte, Roitelet, Beuf de Dion, Berlebot, and Itoy Bertaud of the French; Reillo, Regillo, Rectino, Rostin, Fiorracino, Sericciolo, Ro d'Uccelli, and Stuccafatte, of the Italians; Nelle Konge of Brunnich; Schneekouling, Konickerl, and Zaunehlpfrel, of Kramer; Zaun Sanger of Meyer; Haus und Waldzaunkönig of Brehm; Wren, Vraun or Ran, Cutty, Katy or Kitty Wren, and Kitty, of the English; Dryw of the Welsh.

This bird is found in northern and central Europe. Iceland, Greenland. The Faroe Islands. Resident in Sweden. England, Wales, Scotland, and Ireland, Orkney and Shetland. Spain, France, and Italy. Smyrna. Trebizond.

This familiar little bird, which has become sacred, like the robin, from the confidence which it shows in courting the neighbourhood of man, creeps about the hedges, making small flights, and in its search for insects generally entering the lower part of the hedge and working upwards. Like the Robin it will sing cheerily even in mid-winter, but the frost and snow are sometimes too much for it, and the little creature perishes with cold, which however it avoids by roosting in warm cattle-sheds, for the sake of the animal heat of the inmates, and in other sheltered places.

The nest is placed variously, according to circumstances. Linnaeus says, "nidificat sub terra," and it has been sometimes found in a bank or old road. The materials generally vary with the situation. Thus if the nest be built against the side of a hayrick, hay is used; if against the trunk of a moss-grown tree, that moss is employed. It is large in proportion to the bird, and the shape is generally oval, the top being in the form of a dome, and the entrance by a small hole at the side or sometimes at one end. Feathers generally form the lining. Seven, ten, and even more eggs, white, with a few pale red spots, but sometimes spotless, are here deposited, and about ten days suffice for hatching the brood, 16 of which, it is asserted, have been seen in one nest, a large family for the diminutive parents to rear. But they are most assiduous in collecting food for their young, and though the incubation is short, the female sits very close, depending for her subsistence upon the male, who is in constant attendance on her. Insects and worms are their food.

The feathers in a Wren's tail make a killing trout-fly in the early part of the season.

In the 'Portraits d'Oyseaux' (1557) the following quatrain appears under the cut of this species:—

"Cet oyselet, qu'on nomme Roylelet,
Encontre l'Aigle à debat et querelle.
Touslours est gay, tant masle, que femelle:
Et touslours chante, ayant estre seulet."

The first lines allude to the old fable of the enmity which was supposed to exist between the Wren and the Eagle.

* Wren (*Troglodytes Europæus*).

Regulus cristatus, *Motacilla Regulus*, Linn., is the Roitelet and Roitilet, Huppé of the French, and Pennant thinks, with reason in our opinion, that it is the Souleic, or Soucio, of Belon; it is the Regolo, Red'Uccelli Col Cinfo, Reattino, and Fior-Rancio, of the Italians; Kongsfogel of the Swedes; Fugle-Kongo of Brunnich; Feugleongen of Walter; Gekrönter Sänger, Sommer Zaunkoenig, Nordisches Saffranköpfiges und Goldkopfiges Goldhaneln, of the Germans; Goldhannel of Kramer; Gold-Crested Wren, Golden-Crested Wren, Golden-Crowned Wren, and Kingleet, of the English; Yawigw and Sywigw of the Welsh.

M. Temminck states that this species is sufficiently common in all the countries of Europe up to the Arctic circle. It is an inhabitant of Russia, Siberia, Sweden, Norway, and Denmark, but from these more northern localities there appears to be a kind of autumnal migration to the more temperate parts down to the Mediterranean. It is fairly spread over England, Wales, Scotland, and Ireland, and is found in Orkney and Shetland. It has been received from Trebizond. Edwards looked on it as inhabiting many parts of Asia, and it has been seen in Japan.

This beautiful and active little bird, which is a constant resident in these islands, may be frequently seen busy among the branches, especially of some larch or fir, running actively along and clearing away the insects. It is far from uncommon round London; and if the observer approach cautiously and stand still, he may watch its motions within a very few feet without disturbing it.

The cut of the 'Soucie,' in the 'Portraits d'Oyseaux,' has the following quatrain beneath it:—

"De tous oyseaux l'oyseau plus plein de ioye
Est la Soucie hantant sur les chemins,
Et sur les choux et herbes des jardins.
Il est petit plus qu'autre que lon voye."

Golden-Crested Wren (*Regulus cristatus*).

This bird must not be confounded with the rarer Fire-Crested Wren (*Regulus ignicapillus*), Roitelet triple Bandeau of Temminck, which is also to be seen in Britain. [REGULUS; SYLVIAIDÆ.]

TROGON. [TROGONIDÆ.]

TROGONIDÆ, a family of Insessorial or Perching Birds, remarkable for the beauty of their plumage.

Linnaeus, in his last edition of the 'Systema Naturæ,' placed the genus *Trogon* in his order *Pica*, between *Paradisea* and *Bucco*, in the body of the work; but in his 'Characteres Avium,' at the commencement of the Birds, where he divides the *Pica* into three sections (1, those with walking feet; 2, those with scansorial feet; and 3, those with gressorial feet), he places *Trogon* in the second section, between *Ramphastos* and *Pittacus*. Latham also places it in the same second section, between *Crotophaga* and the Barbets.

In Swainson's 'Synopsis' the *Trogonidæ* are placed between the *Halcyonidæ* and the *Caprimulgidæ*, with the following characters:—

Trogonidæ, the Trogons.—Bill short, triangular, strong; the tips, and generally the margins, toothed; wings very short. Rasorial.

Trogon, Linn.—Both mandibles with their cutting margins serrated; the two anterior toes united as far as the first joint; nostrils concealed by bristles; tarsus entirely feathered. It inhabits tropical America. The Dentirostral type.

Sub-Genera *Harpactes*, Sw.—Bill stronger; both mandibles deeply notched at their tips, but the margins smooth; nostrils perfectly naked; tarsus only half feathered; the anterior toes less united. It inhabits tropical Asia. The Conirostral type.

Apaloderma, Sw.—Bill as in *Trogon*, but the dentitions almost obsolete; feet stronger; the two anterior toes cleft to their base. It is a native of Africa. The Tenuirostral type.

Tennurus, Sw.—Bill as in *Trogon*; tail-feathers forked at their tips, the points diverging. It inhabits South America.

Calurus, Sw.—Bill destitute of serratures; head (typically) with a compressed and elevated crest; upper tail-coverts enormously developed, and hiding the tail. It is a native of South America. The Rasorial type.

Under a line, and between the *Trogonidæ* and the *Caprimulgidæ*, are placed the genera *Crypticus*, Sw., and *Prionites*, Ill.; and Mr. Swainson, speaking of *Crypticus*, remarks that it is by this form, as he suspects, uniting to *Lamprotila*, that the circles of the *Halcyonidæ* and *Trogonidæ* are connected.

Mr. Gould's splendid 'Monograph of the Trogonidæ' was finished in 1833; and in the 'Introduction' to that work he observes, that those birds, as their general structure and their habits sufficiently

indicate, belong to the fissirostral tribe of the *Insessores*. "Greatly insectivorous," says Mr. Gould, "they seize the flitting insect on the wing, which their wide gape enables them to do with facility; while their feeble tarsi and feet are such as to qualify them merely for resting on the branches, as a post of observation whence to mark their prey as it passes, and to which, having given chase, to return. As in all other groups, however, we shall find modifications of the type constituting the ground of generic or subgeneric divisions. . . . If not strictly elegant in form, the Trogons in the brilliancy of their plumage are surpassed only by the *Trochilidæ*: their splendour amply compensates for every other defect. Denizens of the intertropical regions of the Old and New World, they shroud their glories in the deep and gloomy recesses of the forest, avoiding the light of day and the observation of man: dazzled by the brightness of the meridional sun, morning and evening twilight is the season of their activity."

The Trogons are described as solitary birds, extremely jealous of their freedom, never frequenting inhabited or open tracts, and delighting in the silence of deserts. "The interior of the thickest forests is their chosen abode for the entire year. They are sometimes seen on the summit of trees; but in general they prefer the centre, where they remain a portion of the day without descending to the ground, or even to the lower branches. Here they lie in ambush for the insects which pass within reach, and seize them with address and dexterity. Their flight is lively, short, vertical, and undulating. Though they thus conceal themselves in the thick foliage, it is not through distrust; for when they are in an open space, they may be approached so nearly as to be struck with a stick. They are rarely heard to utter any cries, except during the season of reproduction, and then their voice is strong, sonorous, monotonous, and melancholy. They have many cries, from the sound of one of which their name is derived. All those whose habits are known nestle in the hollows of wormeaten trees, which they enlarge with their bills so as to form a comfortable and roomy residence. The number of eggs is from two to four, and the young are born totally naked, but their feathers begin to start two or three days after their birth. The occupation of the male during incubation consists in watching for the safety of his companion, bringing her food, and amusing her with a song, which, though we should call it insipid, is to her without doubt the expression of sensibility. Some of the Couroucous express the syllable 'pio,' repeated many times in succession with a powerful yet plaintive tone. Their accent almost reminds one of the wailings of a child who has lost its way, and it is thus that they cry to each other amidst the silence of the forests. As soon as the young are able to provide for themselves, they separate from their parents to enjoy that solitude and isolation which appear to constitute the supreme happiness of the species. Their aliments are composed of larvae, small worms, caterpillars, coleoptera, and berries, which they swallow entire. The male, at various ages, the female, and the young differ in their plumage, which has given rise to the institution of more species than are really in existence." (Griffiths, 'Cuvier's Animal Kingdom.')

With regard to the geographical distribution of the Trogons, Mr. Gould says that they appear, on general survey, to be divided between America, including its islands, and the islands of the Indian Archipelago; two or three species only having yet been discovered on the continent of India, and those principally inhabiting the countries bordering the Indian Seas. The great nurseries for these birds in the Old World are, he observes, the islands of Ceylon, Sumatra, Java, Borneo, &c.; while over the whole continent of Africa only a single species has yet been discovered. "It is in South America however," continues Mr. Gould, "that we find the greatest number of species, and those of the most exquisite plumage: nor is this all; for it will be further observed that, in accordance with the great geographical distribution thus pointed out, there exist certain characters common to the species inhabiting each region, which, although not very apparent to the unpractised eye, constitute the basis of generic subdivisions, and doubtless have an influence upon their habits and manners."

Previous to the commencement of Mr. Gould's monograph, the number of described species amounted only to 22: to these Mr. Gould has added and characterised 12 others new to science, among which are three additional species of the sub-genus *Calurus*, of which two only were previously known, and those were confounded under one name. The total number of species known when Mr. Gould finished his monograph was 34, 23 of which are inhabitants of America and its islands, 10 of the Indian Islands and India, and one of Africa; but he states in his preface that he has reason to believe that many will yet be discovered, both in the Old and New World, particularly in those remote regions which civilised man has seldom, if ever, visited.

The remarkable plumage and shy habits of the Trogonus did not escape the observation of the ancient Mexicans, in whose mythology one of the species at least (*Trogon pavoninus*) was celebrated. Another species, the Tzinitzean of the Mexicans, *Trogon curucui*, Linn., was employed by them, according to Hernandez (c. xliii.), in the fabrication of the figures and pictures ('imagines') used on festivals, in war, and in their temples. They were probably kept in one of the two houses which formed the Royal Menagerie of ancient Mexico, one of these houses being appropriated to birds which did not live by prey; the other to birds of prey, quadrupeds, and reptiles. Three hundred men, according to Cortes, were employed to take care of

these birds, besides their physicians, who watched their diseases and applied timely remedies. Of the 300 attendants, some procured their food, others distributed it, others took care of the eggs at the time of incubation; whilst others, at certain seasons, plucked their plumage—for the king not only delighted in the sight of so many species, but was very careful of their feathers for the sake of the famous mosaic images and pictures, as well as of the other works which were made of them.

We give a few examples of this extensive family.

Trogon (Calurus) resplendens (Gould). This is one of the most beautiful of the family.

Trogon (Calurus) resplendens.

Upper figure, adult male; lower figure, female or young male. (Gould.)

Mr. Gould, after quoting *Trogon pavoninus*, Temm. ('Pl. Col.' 372) as a synonym, truly observes, that it is scarcely possible for the imagination to conceive anything more rich and gorgeous than the golden-green colour which adorns the principal part of the plumage of this splendid bird; or more elegant and graceful than the flowing plumes which sweep pendent from the lower part of the back, forming a long train of metallic brilliancy.

So rich a dress must be fatally attractive; and accordingly we find that this, the most beautiful of a beautiful tribe, is only found in deep and gloomy forests remote from the haunts of civilised man.

It is a native of Guatemala in Mexico, where it is called Quescal. (Gould.)

T. Mexicanus (Sw.). The old male has the beak bright yellow; throat and ear-coverts black, gradually blending with the green which

Trogon Mexicanus, male. (Gould.)

Trogon Mexicanus. (Gould.)

Upper figure, youthful male; lower figure, female.

covers the chest and the whole of the upper surface; two middle tail-feathers green, with black tips; the two next on each side wholly black; the three outer on each side black, with white tips; wings black, the whole of which, with the exception of the primaries, is finely dotted with gray; a crescent of white encircles the chest; breast, belly, and under tail-coverts, fine scarlet; feet brown. Total length 11 to 12 inches; wing, 5½ inches; tail, 7½ inches.

The young male is distinguished from the adult by the gray freckles on the wings being rather stronger and more inclined to brown on the secondaries; by the extreme outer edge of the primaries being white; and by the tail being regularly barred with black and white, which character is most conspicuous on the outer edges.

The female has the top of the head, throat, chest, and back, dark brown, inclining to olive on the upper surface, and to rufous on the chest; across the chest an obscure band of light gray, the lower part and vent scarlet; wings black, slightly freckled with brown on the outer edges of the secondaries and shoulders; the outer edges of the primaries fringed with white; two middle tail-feathers chestnut-brown, tipped with black; the two next on each side wholly black; the remainder strongly barred with black and white for nearly their whole length; bill yellow, clouded with brown. (Gould.)

It is a native of the north of Mexico.

Mr. Gould states that this species is identical with the *Trogon glaucus* of Lichtenstein.

T. (Apaloderma) Narina, Le Vaill., is a native of South America.

Narina, whose name this is the only known African species bears, was a Gonaqua Hottentot girl, whose charms and manners appear to have produced a great impression on Le Vaillant, and he devotes some pages to her in his 'Travels.'

Mr. Gould quotes him for information respecting the habits and economy of this bird. Its favourite haunts are the thickest parts of the forest; and there it sits, nearly motionless, on a low dead branch during mid-day: in the morning and evening it captures its food, consisting chiefly of locusts, beetles, and other winged insects, with the addition of caterpillars. The account given of the young is extraordinary; for we find it recorded, that "the moment they are excluded they take flight, and follow their parents for a considerable period."

Trogon (Apaloderma) Narina, male and female. (Gould.)

This, if correct, is a rare instance of perfect development among the *Insectores*. We know that the young of the Gallinaceous birds will run as soon as they have left the shell; but their plumage is most imperfect, and it takes a long time to develop the feathers which are to sustain them in flight; whilst in the hulk of *Insectores* cases the nestling is hatched with scarcely anything more than a rudimentary down.

T. (Apaloderma) Reinwardtii, Temm., is a native of Java and Sumatra, where it was discovered by Professor Reinwardt, whose name it bears.

This, Mr. Gould observes, is a scarce bird in cabinets of natural history; and he attributes its rarity to its being very local, remarking that the vast collections brought to this country by Sir T. Stamford Raffles and Dr. Horsfield did not contain an example.

Trogon (Apaloderma) Reinwardtii.

Upper figure, adult male; lower figure, young bird. (Gould.)

TROGONOPHIS (Kaup), a genus of Reptiles.

TROLLIUS, a genus of Plants belonging to the natural order *Ranunculaceæ*. It has a calyx of 5 or more coloured sepals, 5 or more small petals, which are linear, with an obscure depression above the contracted base; the capsules, or follicles, are numerous, and filled with obovate-angular polished seeds. The species are perennial; they are not numerous, and are found generally in the temperate parts of the world.

T. Europeanus, European or Mountain Glove-Flower, has 10 to 15 sepals involuted in the form of a globe; the petals the same length as the sepals, or a little shorter; the leaves 5-parted, with the divisions cut and serrated. This plant is diffused throughout the north of Europe, in moist pastures in sub-alpine districts. It is abundant in the whole chain of the Alps, and is also found in mountainous districts in the north of England, Ireland, Wales, and Scotland. The flowers are large and handsome: in Scotland they are called Luckengowans, or Cabbage-Daisies. In some parts of England, as well as on the continent of Europe, they are gathered on festive occasions for making garlands and decorating the cottages of the peasantry. There are two species, *T. Asiaticus* and *T. Americanus*, which are found in Asia and America.

TRONA, the African name for Native Sesquicarbonate of Soda. [SODIUM.]

TROOPIAL. [MOLOTHRUS.]

TROOSTITE, *Ferruginous Silicate of Manganese*, a Mineral occurring crystallised. Primary form a rhomboid. Colour greenish, yellow, gray, and reddish-brown. Fracture conchoidal. Hardness 5.5. Brittle. Lustre vitreous, inclining to resinous. Translucent to transparent. Specific gravity 3.014 to 3.034. Found at Franklin, New Jersey, U. S. Its analysis, by Dr. Thomson gives:—

Silica	30.650
Protoxide of Manganese	46.215
Peroxide of Iron	15.450
Carbonic Acid and Water	7.300

—99.615

TROPÆOLACEÆ, *Indian Cresses*, a natural order of Plants. The plants belonging to this order are smooth, tender, and herbaceous, with diffuse or twining stems, and alternate-petiolate peltate leaves; the flowers are irregular, axillary, and solitary; the calyx has 5

sepals, the upper one with a long distinct spur; the petals are unequal and irregular, the two upper are sessile and remote, arising from the throat of the calyx, the three lower stalked, and smaller, sometimes abortive; the stamens, 8 in number, perigynous, the filaments distinct; the anthers minute, erect, 2-celled, dehiscing longitudinally; ovary consisting of 3 carpels; style 1, stigmas 3, acute; ovules solitary, pendulous; the fruit is indehiscent, separating into three pieces which surround a common axis; the seeds are large, having no albumen, and filled with the embryo, the cotyledons of which are thick and consolidated together into a single body; the radicle lies within the projections of the cotyledons.

The species of this order differ from *Balsaminaceæ* in their more regular flowers, and in the juicy fruit not having a bony lining to the cells. They resemble *Geraniaceæ* in the possession of a spur. The genera belonging to this order are *Tropæolum*, *Magallana*, and *Chymocarpus*, all of them natives of South America.

Tropæolum majus.

1, branch, showing peltate leaves; 2, flower with calyx, spur, and petals; 3, anther; 4, trilocular fruit with single seeds; 5, petal removed.

TROPÆOLUM (from *τροπῶλον*), a genus of Plants, the type of the order *Tropæolaceæ*. It has a 5-parted calyx, the upper lobe being furnished with a spur; 5 petals, unequal, the three lower ones smallest or altogether absent; 8 stamens, free from the base; 3 carpels, somewhat crose, kidney-shaped, indehiscent, furrowed, roundish; the seed large, filling the cell. The species of this genus, which derives its name from the petiole being inserted into the centre of the leaf, giving it the form of a buckler, are all of them inhabitants of South America. They are all climbing plants.

T. minus, Small Indian Cress or Nasturtium, has peltate-nerved orbicular leaves, the nerves mucronate at the apex; the petals each ending in a bristle-like point. This plant is a native of Peru. It is one of the species of the genus that was earliest brought to Europe, and was cultivated in England by Gerard. It has deep-yellow flowers streaked with orange and red. The whole plant possesses an acrid flavour and odour which are peculiar to this order and the *Cruciferae*. It is on this account that all the species of *Tropæolum* have obtained the common name of *Nasturtium*, which is the name of a genus of plants belonging to *Cruciferae*. The fruit of this plant is pickled, and eaten in the same way as capers; the flowers and leaves may also be eaten as a salad. There is a variety in the gardens with double flowers.

T. majus, Great Indian Cress or Nasturtium, has the leaves peltate-nerved, orbicular, somewhat 5-lobed; nerves not mucronate; petals obtuse. This plant is also a native of Peru. It was introduced into England, according to Peter Collinson, says Smith, in the year 1686.

It has much larger flowers than the preceding, but having the same colour and general appearance. The fruit of this, when green, like the preceding species, is made into a pickle, for which its warm biting character renders it very fit.

T. aduncum, Hooked Indian Cress or Nasturtium, is a native of both Mexico and Peru.

T. tricolorum, the Tricolor Indian Cress or Nasturtium, is a native of Chili at Coquimbo. It has a calyx of an orange-scarlet colour, and tipped with black, whilst the petals are yellow. It is the most showy and handsome of the species.

T. pentaphyllum, Five-Leaved Indian Cress or Nasturtium, has 5 leaflets which are ovate or ovato-lanceolate, entire, and stalked; only 2 petals, which are sessile, acute, quite entire, shorter than the calyx. It is a native of Buenos Ayres, Monte Video, and Brazil in the province of Cisplatine.

T. azureum, Purple Indian Cress or Nasturtium, has the leaves 5-parted, with linear unequal laciniae; equal entire bilobed petals, much longer than the calyx, with a spur shorter than the petals. This plant was discovered by Mr. Miers, and first described in his 'Travels in Chili,' and had been previously seen by Mr. Bridges on the Caraman de Quillota, 4000 feet above the surface of the sea. It is remarkable for its blue flowers.

TROPÆUM, Mr. Sowerby's name for a genus of *Ammonites*, apparently identical with *Crioceratites*, and consisting of those species which have their whorls disconnected, such as *Crioceratites Duvallii*.

Crioceratites Duvallii.

TROPIS (from *τροπῶν*), a small genus of Plants belonging to the natural order *Artocarpaceæ*. The species are found both in the East and West Indies. The flowers are dioecious; spike lax, axillary; male, perigone 3-lobed, spreading, stamens 4; female, perigone 3-lobed; ovary ovate, 1-celled, 1-seeded; stigma bifid. The species form milky trees with alternate entire leaves.

T. Americana, the Ramoon-Trec, is 20 feet high, and a native of the West India Islands, where the leaves and twigs make a wholesome fodder for cattle in the inland woody parts of Jamaica. The drupes are about the size of grapes, and have a pleasant flavour.

T. aspera is a native of and common in all parts of India, sometimes shrubby, but it also grows into a small crooked tree. Its leaves are oblong, unequally serrate, and so scabrous as to be employed by the natives in polishing ivory. The berries are greedily eaten by birds.

T. spinosa another Indian species, less common, is thorny; leaves oblong lanceolate, grossly serrate towards the apex, smooth; female calyx twice the length of the ovary, and eaten by the natives in their curries.

TROPIC BIRD. [PHAETON.]

TROPIDOGASTER. [IGUANIDÆ.]

TROPIDOLEPIS. [IGUANIDÆ.]

TROPIDOLOPI'SMA. [SCINCIDÆ.]

TROPIDOPHORUS. [SCINCIDÆ.]

TROPIDORHYNCHUS. [MELIPHAGIDÆ.]

TROPIDOSAURUS. [SAURIA.]

TROPIDURUS. [IGUANIDÆ.]

TROUT. [SALMONIDÆ.]

TRUFFLE. [TUBERACEÆ.]

TRUMPET-FISH. [CENTRISCUS.]

TRUMPET-FLOWER. [TECORA.]

TRUMPETER (Ornithology), the vulgar name for *Prophias crepitans*, misprinted *Trophias crepitans* in the article AGAMI.

TRUNK OF TREES. [AGE OF TREES; EXOGENA.]

TRYGON. [RAIDÆ.]

TRYPHILINE, a Mineral occurring crystallised and massive. Primary form a right rhombic prism. Massive variety has a coarsely lamellar or crystalline structure, with cleavages parallel to the planes of a right rhombic prism. Colour greenish-gray. Streak grayish-white. Hardness 5.0. Translucent in thin pieces. Specific gravity 3.6. Found at Bodeumais in Bayern. Its analysis gives:—

Phosphoric Acid	41.47
Protoxide of Iron	48.57
Protoxide of Manganese	4.70
Lithia	3.40
Silica	0.53
Water	0.68

TUBE, EUSTACHIAN. [EAR.]

TUBER, in Systematic Botany. [TUBERACEÆ.]

TUBER, in Structural Botany. [EXOGENS.]

TUBERACEÆ, a section of the sub-order *Gasteromycetes*, of the natural order *Fungi*. It is known by its sporangia being membranaceous, and scattered on a serpentine vein-like hymenium, and included in a concrete uterus. The sporidia are at first pulpy. This section includes the genus *Tuber*, the Common Truffle, and *Rhizopogon*, the White Truffle. The species of these genera are not numerous, and are found very generally diffused throughout the temperate parts of the world, and growing buried beneath the soil.

The genus *Tuber* has a closed uterus marbled internally with veins; the sporangia are pedicellate, and confined to the veins.

T. cibarium, the Common Truffle, is known by its surface being warty and of a black colour. It is found buried in the soil of woods, especially beech-woods, sometimes at the depth of ten or twelve inches or more. It is a native of Europe, and is also found in Japan and the East Indies. It grows abundantly in some parts of England. This is one of the few species of the natural order *Fungi* that is used as an article of diet. For this purpose they appear to have been used by the Greeks and Romans; the latter especially considered them a delicacy. It may be however a question as to whether the Roman 'tuber' is really the common truffle. There can however be no doubt that it had a similar form, origin, and use. The truffle when gathered for eating is about the size of a large walnut, and has a very peculiar smell. The flavour is not remarkable, and resembles in some measure that of the mushroom and morel.

T. moschatum, Musk-Scented Truffle, has a roundish smooth blackish appearance, and is a much rarer plant than the last. It has been found in Great Britain, and is characterised by the musky odour which it gives out.

The genus *Rhizopogon* has a sessile uterus, bursting irregularly, and marbled internally with anastomosing veins and sessile sporangia. The *R. albus* of Bulliard is the *Tuber albus* of older botanists, and is called White Truffle, and by some writers, from its Greek appellation, Root-Beard.

TUBERCULARI'NI, a tribe of Plants belonging to the sub-order *Contiomyces*, of the order *Fungi*. The species are characterised by their sporidia being glued together and forming an erumpent disc. It includes the genera *Tubercularia* and *Fusarium*. All the species are found on dead and decaying sticks and branches and trunks of trees, and on the decaying stems of various herbs. The *Tubercularia vulgaris* is a very common fungus, and is found on dead branches, especially those of the currant-tree in the autumn of the year. It forms upon these branches little scarlet or rose-coloured patches which are frequently very conspicuous. The *Fusarium roseum* forms smaller red patches than the last, and is found on the stems of decaying herbaceous plants, as those of the bean, tulip, Jerusalem artichoke, &c.

TUBEROSE. [POLYANTHES.]

TUBICINELLA. [CIRRHIPIEDIA; CETACEA.]

TUBICOLÆ. [ANNELIDA.]

TUBICOLIDÆ (Lamarck), a family of Conchiferous *Mollusca*.

Lamarck observes that the *Tubicolidæ* are undoubtedly conchifers, but of such great singularity, that some among them have been referred to other classes by modern naturalists; and he adds that it is singular

to find a bivalve shell inclosed in a testaceous tube, and still more singular to see it incrustated in or built into the wall of that tube, and concurring to complete such wall.

*Aspergillum Javanum.*

a, the valves incrustated in the tube; *b*, front view of disc.

The singularity of the *Tubicolidæ*, as well as that of the *Pholades*, has, he further remarks, caused a misconception of the real essentials of the shells which belong to the family, namely, two similar, equal, regular valves, articulated by a hinge. As in the shells of the *Tubi-*

*Aspergillum vaginiferum.*

a, the valves incrustated in the tube.

*Aspergillum Novæ Zealandiæ.*

a, the valves incrustated in the tube; *b*, front view of disc.

colidæ there are some which have accessory pieces apart from their valves; so, as one sees in the *Pholades*, some naturalists have taken them for multivalve shells, a notion which has given rise to very odd associations.

The animals of this family are borers, burrowing in stone, wood, and even in thick shells; but some, nevertheless, live in the sand.

The following six genera are arranged by Lamarck under this family:—*Aspergillum*, *Clavagella*, *Fistulana*, *Septaria*, *Teredina*, and *Teredo*.

We here give figures of the more remarkable forms of the genera *Aspergillum*, *Clavagella*, and *Fistulana*, referring to the articles devoted to them for further information.

Aspergillum Javanum is a native of the East Indian Ocean.

The animal of *A. vaginiferum* has been found by M. Rüppel, and it appears to bear much analogy to that of *Pholas*. It is a native of the Red Sea.

A. Nova Zealandia is a native of New Zealand.

Four species of *Clavagella* are recorded by M. Cailliaud.

1. *C. aperta*, Sow. (*C. lata*, Brod.; *C. sicula*, Delle Chiaje).
2. *C. balanorum*, Scacchi.
3. *C. elongata*, Brod.
4. *C. melitensis*, Brod.

They are found in the Mediterranean and the Adriatic seas, at Nice, Venice, Naples, Palermo, and Malta.

We subjoin some of M. Cailliaud's figures, which give more information as to the shell than any yet published.

Clavagella aperta.

a, right valve in a very young state; *b*, the same more advanced, seen in the stone which has been cut to show the excavated part, and the right valve in situ: its young tube has six facets, and develops its first fimbriation or ruffle; *c*, the same still further advanced, also in the stone: its young tube has two ruffles; *d*, the same greatly increased and seen in the stone: a part of the mantle is seen under its right valve and in its excavation, also the great muscle of the mantle and the aperture whence its small rudimentary foot comes forth; the lower extremity of the tube has been cut away to show the siphons terminated in papillae: the tube presents five ruffles and the commencement of two others which the mollusc had not finished; *e*, another specimen, which had entered the stone horizontally, and afterwards had prolonged its tube in a perpendicular direction.

Another specimen of *Clavagella aperta*.

Clavagella Balanorum in an agglomeration of balani. The little tubes above noticed are here seen in the upper figure.

The genus *Fistulana* has the sheath tubular, most frequently testaceous, more convex and closed posteriorly, attenuated towards its anterior extremity, open at its summit, containing a free and bivalve shell; the valves equal, and gaping when they are closed. Animal having at its anterior part two cyathiferous calamules. (Lam.)

M. Deshayes remarks, in his last edition of the 'Animaux sans Vertèbres,' that Lamarck is evidently mistaken in supposing that the calamules, which he believed to exist in the *Fistulana*, were destined to carry the organs of respiration; this error, M. Deshayes observes, is rendered certain by two methods: 1st, the true *Fistulana*, although closed on one side, have never any calamules; 2nd, these calamules belong exclusively to the *Teredines*, and they have their branchiae disposed as in all the *Conchifera*, and not dependent on these calamules.

As an illustration we give *Fistulana clava*, which is a native of the East Indian seas.

The *Fistulana* inhabiting a free tube have been found in sands or hard mud with the small end of the tube uppermost.

Fistulana clava. (Sowerby.)

1, showing the tube with a septum, *a*; 2, outside of the valves; 3, inside of the same. (G. B. Sowerby, 'Genera.') N.B.—Mr. Sowerby figures also a tube of this species without a septum.

TUBIFERA, an order of *Polyparia*.

TUBIPORÆA, or TUBIPO'RINÆ. [POLYPIFERA.]

TUBULARIADÆ. [HYDROIDA.]

TUBULIBRANCHIATA, an order of *Gasteropodous Mollusca*, consists of the genera *Vermetus*, *Magilus*, and *Siliquaria*.

Vermetus (Adanson), has a tubular shell, the whorls of which, in the early age of the animal, form a kind of spire, but afterwards are prolonged into a tube more or less twisted or bent, like those of the tubes of *Serpula*. The shell is ordinarily fixed in an interlaced group of the same species, or partly enveloped in *Lithophytes*. As the animal does not creep, there is no foot properly so called; but that which in the ordinary gastropods forms the tail is bent downwards and carried forward in front of the head, where its extremity expands into a mass furnished with a delicate operculum which closes the entrance to the tube: it has sometimes various appendages, and its operculum is spiny in some species. The head of the mollusc is obtuse, and carries two moderate tentacles, which have the eyes at the sides of their external base. The mouth is a vertical orifice, and beneath it is seen on each side a filament which has all the appearance of a tentacle, but which in reality belongs to the foot. Their branchiæ only form one row, along the left side of the branchial vault.

Cuvier remarks that the species are rather numerous, but not very distinct.

V. dentiferus, a native of Australia, may be taken as an example.

Vermetus dentiferus.
a, shell; *b*, animal. ('Astrolabe.')

A single specimen of *Vermetus lumbricalis*, showing the spire.

Group of *Vermeti*, &c.

The number of species of *Vermetus* recorded by M. Deshayes in his 'Tables' amounts to eight living and one fossil (tertiary, from Angers). *Vermetus* occurs below the chalk: thus Dr. Fitton records six species, from the upper greensand, the gault, the lower greensand, Blackdown, and the Hastings sand.

The following are noticed by Messrs. Quoy and Gaimard ('Zoology of the *Astrolabe*'), in addition to *V. dentiferus*:—*V. zelandicus*, *V. giganteus*, *V. carinatus*, and *V. roseus*.

Vermeti have been found at depths varying from near the surface to twelve fathoms, in sponges, under stones, on shells, in coral-sand, and sand.

Siliquaria (Brug.), resembling *Vermetus* in the head, in the position of the operculum, and in the tubular irregular shell, which has, however, throughout its length a slit which follows all its windings, and

which corresponds with a similar slit in the mantle which covers the branchial cavity. Along the whole length of this slit adheres a branchial comb, composed of a great quantity of foliations, distinct and, as it were, tubular. Linnæus placed them with the *Serpula*, and Cuvier observes that in these later times some have believed that they belong to the class of Annelida. Thus Lamarck supposed *Siliquaria* as well as *Vermilia* to be approximated to the *Serpula*.

Seven recent and ten fossil species have been recorded.

S. muricata, a native of the Indian Seas, may be taken as an example.

Siliquaria muricata.

Species of this genus have been found in sponges.

Magilus. [MAGILUS.]

TUBULIPORA. [POLYZOA.]

TUBULIPORADÆ. [POLYZOA.]

TUCUTUCO. [MURIDÆ.]

TUFF, or TUPA. The accumulations of scoria and ashes about a volcanic crater, which are re-aggregated so as to make a coherent or solid mass, are termed Volcanic Tuff. Similar but more ancient aggregations of the products of heat, re-aggregated into firm, solid, or even highly compact rock, are called Trap Tuff.

TULIP. [TULIPA.]

TULIPA, a genus of Plants belonging to the natural order *Liliacæ*. This name is a corruption of the Persian word Thoulghan, or Tolehan, which is the name the plants of this genus bear in Persia. The Persian word also signifies a turban. The genus is known by its perianth being composed of six sepals. The stigma is 3-lobed; the seeds are smooth, and it has neither nectary nor style. All the species are herbaceous plants, developed from a bulb; the flowers are mostly solitary, seated on a lengthened scape, at the base of which the leaves, not numerous, are developed. About thirty species have been described.

T. sylvestris, the Wild Tulip, has the stem 1-flowered, somewhat drooping; the leaves of the perianth ovate-acuminate, hairy at the extremity, the stamens hairy at the base. This is the only species of tulip that is a native of Great Britain. In England it occurs in the counties of Norfolk, Suffolk, Hertfordshire, and Middlesex, in a chalk soil. It has also been found in Scotland. It is found in the southern parts of Germany, in Switzerland, Italy, and France. It has yellow flowers, and blooms in April and May. It increases itself by throwing out a long stout fibre from its root, at the extremity of which a bulb is developed, and thus a new individual is produced at a considerable distance from the parent plant.

T. Oculus Solis, the Agen Tulip, has a 1-flowered glabrous stem; oblongo-lanceolate leaves; the stamens smooth; the exterior leaves of the perianth acuminate, the interior ones obtuse. This species was not known to Linnæus, and was first distinguished by St. Amans. It was found at Agen in France, and also grows wild in Italy, Germany, and other parts of Europe. The flowers are large and bell-shaped, of a fine scarlet-red colour, each petal marked with a broad black yellow-edged spot at its base. It blossoms in April and May.

T. suarcolens, the Early Dwarf, or Van Thol Tulip, is a native of the south of Europe. It blooms in March and April.

T. Celsiana, Small Yellow Tulip, has a solitary, mostly erect, flower; the leaves of the stem lanceolate; leaves of perianth greenish, lanceo-

late; the stamens slightly hairy above the base. This plant blossoms in March or April, and is a native of the south of Europe, and of the banks of the Volga. It was known to Clusius, Bauhin, Magnol, and Tournefort, but Linnæus confounded it with the wild tulip.

T. Clusiana, Red and White Italian Tulip. This tulip was confounded by Linnæus with the *T. Gesneriana*.

T. biflora, the Two-Flowered Yellow Tulip, is a native of the salt deserts about the Volga, and is found in company with *T. Celsiana*. The flowers are fragrant.

T. Gesneriana, Common Garden Tulip, has the stem 1-flowered and smooth, as well as the petals and filaments; the flower erect, the leaves ovato-lanceolate, glaucous and smooth; the lobes of the stigma decurrent and deeply divided. Of all the species of tulip this one is the best known, and has perhaps had more attention bestowed upon it than any other plant that produces only flowers. This species of tulip grows wild in the Levant, and appears to have been cultivated by the Turks in their gardens from an early period.

The Tulip was first introduced into France in 1611. It does not appear at what time it was first carried to Holland, but the Dutch were early in the habit of sending to Constantinople for tulip-seeds. It was in this country that the Tulip was destined to make the greatest impression. In the early part of the 17th century the passion for the possession of these plants became so strong, that dealing in them became one of the most important money speculations, and the bulbs of tulips were sold and resold at enormous prices, in the same manner as stocks are on the Stock Exchange of England. It became in fact a gambling transaction, in which persons ventured their capital, in the hope that particular kinds of tulips would realise a higher price. This practice was not carried on throughout Europe, but was confined to the Netherlands, and rose to its greatest height in the years 1634, 1635, 1636, 1637. Beckmann, in his 'History of Inventions,' gives an account of this remarkable tulipomania, as it was called. One variety of tulip, called the Viceroy, was exchanged for articles valued at 2500 florins. [TULIP, in ARTS AND SC. DIV.]

TULIP-TREE. [LIRIODENDRON.]

TUNGSTEN, a Metal. It was first obtained in its pure state in 1781. Its name is derived from 'tung sten,' two Swedish words, signifying 'heavy stone,' from the weight of its ore. It is also called Scheelite, in honour of the chemist Scheele.

Tungsten is found in combination with iron, lead, and lime, constituting Wolfram, Tungstate of Lead, and Tungstate of Lime. It also occurs sparingly in some ores of columbium, as in certain varieties of the minerals pyrochlore, columbite, and ytthro-columbite. It is met with in very small quantities as an ochre, or as tungstic acid, forming a yellow powder on other Tungsten ores.

No use in the arts has been made of this metal or its compounds. Tungstic acid is a fine yellow, even brighter than chrome yellow, but it turns green on exposure to the sun's rays.

Tungstate of Lime occurs in square octahedrons. Cleavage octahedral, perfect. Colour yellowish-white or brownish. Brittle. Hardness 4 to 4.5. Specific gravity 6.075. It is composed of Tungstic Acid 7.8; Lime 19.06. Infusible alone, or only, on the thinnest edges.

TUNICATA, a family of Acepbalous *Mollusca*. The following graphic description is given of these interesting forms of animal life in Forbes and Hanley's 'British Mollusca':—"Rarely is the dredge drawn up from any seabed at all prolific in submarine creatures, without containing few or many irregularly-shaped leathery bodies, fixed to sea-weed, rock, or shell, by one extremity or by one side, free at the other, and presenting two more or less prominent orifices, from which, on the slightest pressure, the sea-water is ejected with great force. On the sea-shore when the tide is out, we find similar bodies attached to the under surface of rough stones. They are variously, often splendidly coloured, but otherwise are unattractive, or even repulsive in aspect. These creatures are *Ascidia* properly so called. Numbers of them are often found clustering among tangles, like branches of some strange semitransparent fruit. They are very apathetic and inactive, living upon microscopic creatures drawn in with currents of water, by means of their ciliated respiratory organs. The leathery case is often encrusted with stones and shells, decorated with parasitical though ornamental plumes of corallines, and not seldom perforated by bivalves, which lodge themselves snugly in the tough but smooth skin. It is the analogue of the true shell of conchiferous *Mollusca*. It is a sac, closed except at two orifices, one of which is branchial, the other anal. This elastic, gelatinous, or coriaceous envelope is called the test, and incloses a second tunic or mantle, which is muscular, and adheres to the first only near the orifices. The branchial sac lines the interior of the mantle in part; it is both respiratory and pharyngeal. The remainder of the cavity is occupied with the principal organs of digestion, circulation, and generation. The chief nervous centre is situated between the two openings of the muscular tunic. The sexes of *Ascidia* are distinct." For our present knowledge of the structure and relations of these animals we are greatly indebted to Savigny. They were not however unknown to Aristotle. In the 'Historia Animalium,' he observes, under the head of Testaceous Animals (τὰ ὀστρακοδέρμα), that "there are some, such as those called *Τύββα*, which are so entirely surrounded by their test or envelope as to have no part of their flesh exposed." So far, as Mr. M'Leay remarks, this accurately drawn character may apply to

the whole of the *Tunicata*. But Aristotle afterwards proceeds to a more definite description of the *Tethya*:—"But of all these animals (the Ostracoderms), those which are called *Tethya* have the most remarkable nature; for with them alone is the body entirely concealed in the test. This test or envelope (τὸ δοττακον) is between the texture of leather and shell, and may be consequently cut like a piece of tough hide. The animal adheres to the rocks by its test, and has two passages or orifices (πόροι), distant from each other, and so small as not to be easily visible: by means of these it imbibes and discharges the water. On opening one of these animals, the inside presents, in the first place, a membrane composed, as it were, of nervures (διμένα νεύρα), and communicating with a fleshy intestine (τὸ σαρκώδες); so that the intestine of the *Tethyon* appears contained in the reticulated membrane. Although indeed the flesh is alike in all testaceous animals, this intestine resembles in form that of none of them. It is suspended at two places, namely, to the above-mentioned membrane, and to the muscle which proceeds from the side (literally, 'to the skin from the side'); and wherever it adheres to either of these it is narrowest. At each point of suspension this intestine tends towards those orifices which lead to the outside of the test, and by which it receives and discharges the food and water; so that if one of these apertures be the animal's mouth, the other must be its anus. One of these orificial processes (the branchial orifice) is thicker than the other. Within the cavity also of one or other of them there is a certain small cobering substance which divides it."

Mr. McLeay, who, in his 'Hore Entomologica,' thus translates a passage presenting almost insuperable difficulties to any but a zoological scholar, observes, that "the membrane, composed as it were of nervures," is a good description of the beautifully reticulated membrane which forms the branchial of the *Tethya*. Aristotle, he adds, appears however by some mistake to have considered the branchial pouch as surrounding the intestine; and he remarks that he suspects that the small cohering or continuous substance which Aristotle alludes to immediately after the mention of that part which Mr. McLeay considers to be the branchial orifice, is the valvule of the anal orifice.

Dr. Fleming has given a very good view of this natural group in the article 'Mollusca' of the supplement to the 'Encyclopædia Britannica.'

Synopsis of the Sub-Genera.

Normal Group.	
1. Branchial pouch with more than eight folds. Tentacula compound. Liver distinct.	1. <i>Cynthia</i> , . . . { Reticulation of the branchial pouch continuous. 2. <i>Cesira</i> , Sav. . . { Reticulation of the branchial pouch interrupted.
	3. <i>Styela</i> , Sav. . . { Ovaries several, one at least on each side of the body.
Aberrant Group.	4. <i>Pandocia</i> , Sav. . . { Ovary unique, that is, only the right one, which is comprised in the intestinal loop.
	5. <i>Dendrodia</i> , McLeay . . . { Ovary unique, that is, only the left one, which is ramose or branched, and situated between the branchial pouch and the mantle.

"The *Tunicata*," says Dr. Fleming, "agree with their contiguous group the *Mollusca* in the remarkable variation that exists in their system of generation. Like every other solitary character that can possibly be adopted for the groundwork of a zoological system, the mode of generation ought to rise in importance only in inverse proportion to its degree of variation. In a group of animals for instance, where it varies according to the species, it is evidently of less importance, as affording natural characters, than among those groups where it remains less subject to variation. When the naturalist happens to consider that he ought always to obtain his group before he attempts to find its character, he is sure to perceive this truth; and it is on this very principle that Savigny, with his usual discrimination, has proceeded in the above natural arrangement of the genus *Ascidia*, which I have done little more than borrow from him. To this naturalist, whose works I cannot too often recommend to the careful attention of zoologists as models for imitation and true examples of the method in which natural history ought to be studied, I would willingly have dedicated the following genus" [*DENDRODIA*], "but his name happens to have been employed in other branches of the science." ('Linnæan Transactions,' vol. xiv.)

Mr. Broderip and Mr. G. B. Sowerby have described a curious form belonging to this natural group.

Group, *Tunicata*.—Family, . . . ?—Genus, *Chelyosoma*.

Generic Character.—Body sessile, fixed, involved in a coriaceous test or envelope dividedly laminate above; orifices conical, each closed with six trigonal valvules.

C. MacLeayanum is elongate-ovate, affixed at the base, flat above, octopartite, the laminae striated; orifices prominent. It is found in the Arctic seas, adhering to stones.

This animal comes nearest to the *Tethya* above noticed, but there are no traces of tentacula surrounding the branchial orifice. It differs

from the *Thalida* inasmuch as the mantle seems to adhere to the orifices only, and, instead of a simple valvule, each orifice of *Chelyosoma* is furnished with a complicated one. From the *Ascidia* it differs inasmuch as both its orifices are surrounded by six valves, instead of being quadrid.

Chelyosoma MacLeayanum.

a, side view; b, seen from above; c, interior of valvule.

Forbes and Hanley, in their 'History of British Mollusca,' describe three genera of *Tunicata*:—

1. *Ascidia*.—Body sessile, covered with a coriaceous or gelatinous tunic; branchial orifice 8-lobed and 6-lobed. There are 16 species of this genus found on the British coasts.

2. *Molgula*, E. Forbes.—Body more or less glohular, attached or free, with a membranous tunic, usually invested with extraneous matter; orifices on very contractile and naked tubes; the branchial 6-lobed, the anal 4-lobed. Two species are British.

3. *Cynthia* [CYNTHIA], of which there are 13 species. [CLAVELINIDÆ; BOTRYLLIDÆ; MOLLUSCA; MALACOLGY; BOLTONIA.]

The compound (and most probably all the) Ascidians, in their first state of development, after leaving the egg, assume the form of Tadpoles, and are locomotive by means of a vibratile tail, which they cast off when they quit the larva state and assume the sessile condition.

Tadpole of *Amaroucium proliferum*, newly hatched (highly magnified).

a, tegumentary body of the trunk seen within the pouch; b, pouch inclosing the vitellus, and forming the tunic of the body of the larva; b', appendages terminating in suckers and enabling the animal to fix itself; a*, tail formed by a prolongation of the tegumentary body, and inclosing a tubular appendage of the vitelline sac. (Milne-Edwards.)

This metamorphosis was observed by Sir John Graham Dalyell, both in a solitary and compound Ascidian, namely, in *Ascidia papilla* (solitary) and in *Aplidium verrucosum* (compound). (See 'Edinburgh New Philosophical Journal,' January, 1839, vol. xxvi., p. 152.) But in 1828 Messrs. Audouin and Milne-Edwards had proved that the compound Ascidiaria are at their birth endowed with sufficiently extensive locomotive faculties, and that, in the progress of age, they underwent a true metamorphosis ('Ann. des Sciences Nat.,' 1823, tome xv., p. 10); and M. Sars, as well as Sir John Graham Dalyell, subsequently verified the fact, which had been doubted by certain naturalists. The observations of M. Sars were made upon the *Botryll* of the Norwegian coasts. The metamorphosis of these animals is admirably described and figured in the beautifully-illustrated paper by M. Milne-Edwards, entitled, 'Observations sur les Ascidies composées des Côtes de La Manche,' read before the French Academy of Sciences on the 11th of November, 1839, wherein the structure and general physiology of these highly-interesting animals is explained in a masterly manner.

Amaroucium proliferum, natural size.

Mass of the same species, magnified. (Milne-Edwards.)

A fossil, supposed to belong to the *Tunicata*, has been figured and described by Sir Roderick Murchison in his 'Silurian System,' to which the name *Ischadites Königii* has been given.

Ischadites Königii.

TUNNY. [SCOMBRIDÆ.]

TUPAIA. Sir T. Stamford Raffles's name for a genus of *Mammalia* which Dr. Horsfield places among Cuvier's Insectivorous Carnassiers, the *Fera* of Linnaeus, and the *Falculata* of Illiger. It has the following generic characters:—Head oblong, depressed. Snout long, equally attenuated; nostrils lateral, semilunar. Eyes very large, and rather prominent. Ears large and oblong. Body cylindrical, covered with close fur and soft hairs. Tail longer than the body, linear, compressed.

Feet plantigrade and pentadactyle, the soles naked, the toes compressed and the claws falcular.

Head of *Tupaia tana*, natural size.
a, profile; b, seen from above. (Horsfield.)

In the Malayan language the name of *Tupai* is a general term for various small animals which have the external form and agility of the squirrel.

T. Javanica; Bangsering, or Sinsring, of the Javanese. Dr. Horsfield says that this species has the appearance of a sprightly animal, a character with which its manners, as far as they are known, perfectly agree. "Its body," says Dr. Horsfield, "is graceful and handsomely formed, and its limbs are slender and fitted for great agility: its size and exterior habits so nearly resemble the individuals of that family which Illiger has denominated *Animalia Agilia*, that, on a superficial view, it has been considered to belong to it. Our animal agrees with one of the most numerous sections of this family, the Squirrels, in the form of the body, the proportional length of the extremities, the breadth of the tail, and the faculty of carrying it on the back as a plume; but the succeeding details will show that its structure and organisation are essentially different."

Dental Formula:—Incisors, $\frac{2}{6}$; Canines, $\frac{2}{2}$; Molars, $\frac{14}{12}$.

Teeth of *Tupaia Javanica*.

a, upper jaw: in this view the animal is supposed to be laid on its back, and the spectator to be looking down on the upper jaw; b, lower jaw seen from above. (Horsfield.)

Dr. Horsfield describes the claws as sharp, compressed, and curved; and, in comparison with those of *Sorex* and several other genera of this order, of considerable strength: they are, he observes, individually supported by a small protuberance similar to that which is found in the *Tarsii*; and the construction of the claws in the Bangsering is adapted, he remarks, to the same food and habits as those of the other species of *Tupaia*. The linear tail, of the same length as the body, is compressed, with the hairs spreading far on each side; but, adds Dr. Horsfield, it is less full and ornamental than in the Squirrel. The fur of the Bangsering is close, silky, and delicate, with a few longer, more rigid, and darker-coloured hairs dispersed among the long and straight hairs closely applied to the skin, with which the back, neck, sides, tail, and extremities above are furnished. The upper parts are brown, slightly diversified with gray of different shades; the lower

parts dirty white, with a slight tint of grayish: the tail agrees with the upper parts; and the scapular line, which is nearly an inch long, agrees with the neck.

Head of *Tupaia javanica*. (Horsfield.)

a, fore foot of *Tupaia javanica*; b, hind foot of the same. (Horsfield.)

The Bangaring fell under Dr. Horsfield's observation during an early period of his researches in Java. In traversing the province of Blambangan, in 1806, he discovered it in the extensive forests which almost entirely cover the eastern extremity of the island; and he thinks that its range, though it may not be confined exclusively to that province, is extremely limited.

Tupaia javanica. (Horsfield.)

Sir Stamford Raffles states that a tame *Tupaia ferruginea* was suffered to go about at perfect liberty, ranged in freedom over the whole house, and never failed to present himself on the breakfast and dinner-table, where he partook of fruit and milk.

TUPINAMBIS. [MONITORIDÆ.]

TUPISTRA, a genus of Plants nearly allied to the natural order Smilacæ, and referred by Lindley to the order Liliacæ.

TURBINA'CEA, M. De Blainville's name for his sixth family of Polythalamacæ, including the genera *Cibicides* and *Rotalites*, microscopic Foraminifera. Lamarck's Turbinacæ might include M. D'Orbigny's *Scissurella*. [TURBINIDÆ.]

TURBINELLA. [SIPHONOSTOMATA.]

TURBINIDÆ, a family of Gasteropodous Mollusca.

Linnaeus places his genus *Turbo*, in his last edition of the 'Systema Naturæ,' between *Trochus* and *Helix*, with the following characters:—Animal a *Limax*, or Slug. Shell univalve, spiral, solid. Aperture narrowed, orbiculate, entire.

The Turbinacæ of Lamarck belong to his first section of Trachelipoda, and constitute the last family of his Phyllophagous or Plant-Eating Trachelipoda, those, namely, which in general have no proboscis, but a muzzle with two jaws, and which appear to be simply herbivorous; those, finally, whose shell offers at the base of its aperture neither notch directed backwards nor any canal whatever. All are marine shells, conoid or turriculate, and appear to be provided with an operculum. When one of these shells is placed on its base, its axis is

always inclined more or less, and is never vertical. ('Animaux sans Vertèbres.')

Lamarck's Turbinacæ consist of the genera *Solarium*, *Rotella*, *Trochus*, *Monodonta*, *Turbo*, *Planaxis*, *Phasianella*, and *Turritella*.

The Sabots (*Turbo*, Linn.) of Cuvier comprise the Sabots properly so called (*Turbo*, Lam.); *Pleurotomaria*, of which he considers the *Scissurella* of D'Orbigny living species; *Turritella*, Lam.; *Scalaria*, Lam., and the terrestrial and fresh-water genera *Cyclostoma*, Lam., and *Valvata*, Müller. [TROCHIDÆ.]

The Cricostomata of M. De Blainville consist of the genera *Turbo*, *Pleurotomarium*, *Delphinula*, *Turritella*, *Proto*, *Scalaria*, *Vermetus*, *Siliquaria*, *Magilus*, *Valvata*, *Cyclostoma*, and *Paludina*.

In Woodward's 'Manual of the Mollusca' the Turbinidæ are thus defined:—Shell spiral, turbinated or pyramidal, nacreous inside; operculum calcareous and paucispiral, or horny and multispiral. Animal with a short muzzle; eyes pedunculated at the outer bases of the long and slender tentacles; head and sides ornamented with fringed lobes and tentacular filaments (cirri); branchial plume single; lingual ribbon long and linear, chiefly contained in the visceral cavity; median teeth broad; laterals 5, denticulated; uncini very numerous (sometimes nearly 100), slender, with hooked points.

The shells of nearly all the Turbinidæ are brilliantly pearly, when the epidermis and outer layer of shell are removed. Many of them are used in this stato for ornamental purposes.

The following genera are embraced in the family thus defined:—

Turbo.—Shell turbinated, solid; whorls convex, often grooved or tuberculated; aperture large, rounded, slightly produced in front; operculum shelly and solid, callous outside and smooth, or variously

Turbo marmoratus.

a, view of back; b, view of mouth with the operculum in; c, inside of operculum.

grooved and mammillated, internally horny and paucispiral. In *T. sarmaticus* the exterior of the operculum is botryoidal, like some of the infusaceous deposits of petrifying wells. Animal with pectinated head-lobes.

There are 60 recent species which are found principally in tropical seas. The fossil species amount to 390, found in the Lower Silurian rocks.

T. marmoratus has the shell subovate, very ventricose, imperforate, smooth, green marbled with white and brown or subfasciated; the last whorl transversely nodulous in a triple series, the upper nodules greatest; the lip at the base flattened into a short subreflected tail-like process; mouth silvery.

This shell when deprived of its external layer exhibits a silvery, iridescent, and very brilliant naere.

T. torquatus has the shell orbiculate-convex, broadly and deeply umbilicated, transversely sulcated, substriated with close-set longitudinal lamellæ of a gray-green colour; whorls above, coronated; the last girth with a median carina; spire blunt at the apex. (Lam.)

The shell, when deprived of its first layer, is beautifully nacreous.

This species, which grows to a large size, inhabits King George's Sound. Only a few individuals were found alive.

Turbo torquatus.

a, Shell with the animal, seen from below; b, the animal out of the shell; c, outside of the operculum; d, inside. ('Astrolabe.')

T. Cookii has the shell orbiculate-convex, with a ventricose dilated base, longitudinally plicate, rough, rufo-fuscescent; the plications very frequent, close-set, oblique, imbricato-squamous; the whorls convex; lower surface rather convex, concentrically rugous, and imperforate. (Lam.)

The animal has long filiform white tentacles, dotted with red-brown, without palmettes at their internal part; the eyes pediculated. The mouth is elongated in form of a proboscis, or is widened into a hood. It is white, striated transversely with black. The foot is large, yellowish, dotted with brown below, with a median line of the same colour.

The operculum is oval, rounded at one of its extremities with an oblong fosset, sometimes paucispiral. It is white and greenish. Its spiral is less pronounced than in the greater portion of the other Turbines.

Messrs. Quoy and Gaimard found this species in great numbers in Tasman's Bay, New Zealand, in the Bight of the Astrolabe (L'Anse-de-l'Astrolabe), and on the reefs of the Passe-des-Français.

Turbo Cookii.

a, Shell; b, shell seen from below, animal nearly in profile; c, anterior part of animal seen from below; d, inside of operculum; e, outside. ('Astrolabe.')

Phasianella.—Shell elongated, polished, richly coloured; whorls convex; aperture oval, not pearly; inner lip callous, outer thin; operculum shelly, callous outside, subspiral inside.

Animal with long ciliated tentacles; head-lobes pectinated, wanting in the minute species; neck-lobes fringed; sides ornamented with 3 cirri; branchial plume long, partly free; foot rounded in front, pointed behind, its sides moved alternately in walking; lingual teeth even-edged; laterals 5, hooked, denticulated; uncini about 70, gradually diminishing outwards, hooked, and denticulated.

The *Phasianella* are always smooth. This polish, and still more their continual movements, prevent them from being covered with *Serpula*, *Flustra*, and other parasites which encrust sluggish shells. This agitation makes it difficult for them to preserve the contour of their aperture perfect, for it is very frail.

These are lively active animals, and voracious withal, for they were taken in nets baited with flesh let down into the sea. Their foot, endowed with great mobility, is elongated like a proboscis; its great peculiarity is its faculty of moving in two portions as it were, that is

to say, each of its sides advances separately and successively; and a longitudinal gutter may be perceived on its lower surface.

On the coasts of Australia, the *Phasianellæ* found at King George's Sound are larger and less numerous than at Port Western. They are few in number on the coasts of Van Diemen's Land. The operculum is always calcareous.

P. bulimoides. Shell oblong-conical, smooth, pale yellow, transversely banded; the bands frequent and diversely variegated and spotted; spire acute at the apex.

The animals are generally of a fine green nearly throughout. One will have more white dots on the foot, and another a violet or reddish spot on the lateral fringes on the foot; a third will have this organ yellowish and slightly fringed upon the borders. In all the tentacles are slender and long, the ocular peduncles stout and button-shaped, the palmettes lacinated. The muzzle, which is elongated a little in the form of a proboscis not retractile, can also modify itself into the shape of a rounded scutcheon (écusson). The fringes of the sides of the feet are very finely lacinated, and sometimes present brown ramifications of vessels; they carry three greenish filaments on each side.

The operculum is oval, calcareous, slightly convex, white, and covered for a portion of its contour by a fleshy lamina of the foot which supports it.

They are very common at Port Western, being the species above alluded to, and larger at King George's Sound.

Woodward records 25 recent and 70 fossil species.

Phasianella bulimoides.

a, animal and shell, seen from below; b, the same seen from above; c, shell, d, operculum. ('Astrolabe')

Imperator has the shell trochiform, thick, with a flat or concave base; whorls keeled or stellated; aperture angulated outside, brilliantly pearly; operculum shelly. The species, about 20 in number, are found in South Africa, Australia, and New Zealand.

Trochus. [TROCHIDÆ.]

Rotella.—Shell lenticular, polished; spine depressed; base callous; lingual teeth 13; uncini numerous, subequal. There are 10 species found in India, the Philippines, China, and New Zealand.

Monodonta.—Shell turbinated, few-whorled; whorls spirally grooved and granulated; lips thickened internally and grooved; columella toothed, more or less prominently and irregularly; operculum horny and many-whorled. There are 10 species found in West Africa, the Red Sea, India, and Australia.

Delphirula.—Shell orbicular, depressed; whorls few, angulated, rugose, or spiny; aperture round, pearly; peristome continuous; umbilicus open; operculum horny, many-whorled. Animal without head-lobes; sides lobed and serrated. Twenty recent species, and about thirty fossil species have been recorded. *Liotia*, *Collonia*, and *Cyclostrema* are sub-genera.

Adeorbis.—Shell minute, not nacreous, depressed, few-whorled, deeply umbilicated; peristome entire, nearly continuous, sinuated in its inner side, and slightly so externally. Operculum shelly, multi-spiral.

Euomphalus.—Shell depressed or discoidal; whorls angular or coronated; aperture polygonal; umbilicus very large; operculum shelly, round, multi-spiral. (Salter.)

There are 80 fossil species.

Stomatella.—Shell ear-shaped, regular; spire small; aperture oblong, very large and oblique, nacreous; lip thin, even-edged; operculum circular, horny, multi-spiral. They are found on reefs and under stones at low-water.

Twenty species are recorded from the Cape, India, North Australia, China, Japan, and the Philippines.

Broderipia, Gray.—Shell minute, limpet-shaped, with a posterior submarginal apex; aperture oval, as large as the shell, brilliantly nacreous. Three species are found in the Philippines, Grimwood's Island, and the South Seas. (Cuming).

TURBINO'LIA. [MADREPHYLLIGÆ.]

TURBINOLIDÆ. [POLYPTERA.]

TURBINOLOPSIS. [MADREPHYLLIGÆ.]

TURDUS. [MERULIDÆ.]

TURDUS SORDIDUS. [SWALLOW-TRIBE.]

TURF. [BOG.]

TURGITÆ, a Mineral from the Ural, consisting of peroxide of iron.

TURK'S CAP LILY. [LILIUM.]

TURKEY. [PAVONIDÆ.]

TURKEY-BERRIES. [RHAMNUS.]

TURKEY-BUZZARD (*Vultur aura*, Linn.); genus *Cathartes*, III.

Under the name of *V. aura*, two species at least have been confounded, one the true *V. aura*, and the other the *Urubu*, *V. atratus*; the former is figured by Wilson, pl. 75, f. 1, and the latter in the same plate, f. 2.

Mr. Darwin ('Journal,' 1839), after a most interesting account of the habits of the Caracaras (*Polyborus*), gives the following account of the two birds:—"We have now only to mention the Turkey-Buzzard (*V. aura*) and the Gallinazo. The former is found wherever the country is moderately damp, from Cape Horn to North America. Different from the *Polyborus Brasiliensis* and *Chimango*, it has found its way to the Falkland Islands. The Turkey-Buzzard is a solitary bird, or, at most, goes in pairs. It may at once be recognised from a long distance, by its lofty, soaring, and most elegant flight. It is well known to be a true carrion-feeder. On the west coast of Patagonia, among the thickly-wooded islets and broken land, it lives exclusively on what the sea throws up, and on the carcasses of dead seals. Wherever these animals are congregated on the rocks, there the vultures may be seen. The Gallinazo (*Cathartes atratus*) has a different range from the last species, as it never occurs to the southward of 41° S. lat. Azara states that there existed a tradition that these birds, at the time of the conquest, were not to be found at Monte Video, but that they subsequently followed the inhabitants from the more northern districts. At the present day they are numerous in the valley of the Colorado, which is 300 miles due south of Monte Video. It seems probable that this additional migration has happened since the time of Azara. The Gallinazo generally prefers a humid climate, or rather the neighbourhood of fresh water: hence it is extremely abundant in Brazil and La Plata, while it is never found on the desert and arid plains of Northern Patagonia, excepting near some stream. These birds frequent the whole Pampas to the foot of the Cordillera, but I never saw or heard of one in Chili; in Peru they are preserved as scavengers. These vultures certainly may be called gregarious, for they seem to have pleasure in society, and are not solely brought together by the attraction of a common prey. On a fine day a flock may often be observed at a great height, each bird wheeling round and round without closing its wings, in the most graceful evolutions. This is clearly done for sport-sake, or perhaps is connected with their matrimonial alliances."

Nuttall remarks that the Turkey-Buzzard has not been known to breed north of New Jersey in any of the Atlantic States; and he says that they seek out the swampy solitudes, and, without forming any nest, deposit from two to four eggs in the stump of a hollow

tree or log, on the mere fragments of rotten wood with which it is ordinarily strewn. Occasionally, in the Southern States, they have, he tell us, been known to make choice of the ruined chimney of a deserted house for this purpose. The eggs, which are described as being larger than those of a turkey, are yellowish-white, blotched irregularly with dark-brown or blackish spots, at the larger end chiefly. The male often attends while the female is sitting; and, if not materially disturbed, they will continue to occupy the same place for several years in succession. The young, which are covered with a whitish down, will, like their parents, eject the filthy contents of their stomachs over those who molest them. ('Manual of the Ornithology of the United States and of Canada.')

Turkey-Buzzard (*Fulmar aura*).

TURKEY-HONE, a common name of *Whetstone* or *Novaculite*. [SLATE.]

TURMERIC. [CURCUMA.]

TURNERA. [TURNERACEÆ.]

TURNERACEÆ, a natural order of Exogenous Plants. It possesses an inferior calyx, often coloured, having 5 equal lobes imbricated in æstivation; 5 petals, which are inserted into the tube of the calyx, equal and twisted in æstivation; 5 stamens, which are also inserted into the calyx below the point of insertion of the petals, with which they alternate with oblong 2-celled anthers; a superior ovary 1-celled, with 3 parietal placentæ, indefinite ovules, 3 or 6 styles, which cohere more or less together; a 3-valved capsule, the valves bearing the placentæ in the middle, and opening from about as far as the middle of the capsule; seeds with a reticulated testa and a membranous aril, and a slightly-curved embryo lying in the midst of fleshy albumen, and having the radicle turned towards the hilum. This order has only two genera, *Turnera* and *Piriqueta*. All the species are herbaceous plants, in some instances having a tendency to become shrubby.

Turnera ulmifolia.

1, cutting, showing axillary solitary flowers; 2, section of flower, with ovary, style, and multifid stigma; 3, section of capsule; 4, valves with parietal placentæ; 5, seed with reticulated testa and aril.

The affinities of this order are with *Fourquieraceæ*, *Cistaceæ*, *Malvaceæ*, *Loasaceæ*, and *Passifloraceæ*, especially with the two last. The species of this order are exclusively natives of the West Indies and South America.

TURNERITE, a Mineral occurring in attached crystals. Primary form an oblique rhombic prism. Cleavage parallel to both diagonals of the prism. Fracture conchoidal. Hardness 4·5 to 5·0; readily scratches phosphate of lime. Colour yellow or brownish-yellow. Lustre vitreous. Translucent; transparent. Dissolves almost entirely in hydrochloric acid. It is found at Mont-Sorel, in the department of Isère. It consists principally of alumina, lime, and magnesia, with a small quantity of iron, and a minute portion of silica.

TURNIP. [BRASSICA.]

TURNIP-FLY. [HALTICA.]

TURNIX. [PERDIDICÆ.]

TURNSOLE. [HELIOTROPICUM; SUN-FLOWER.]

TURNSTONE. [CHARADRIADÆ.]

TURPENTINE is a name applied to the resinous secretion which exudes from most of the species of Coniferous Plants. [CONIFERÆ.] It consists of a mixture of oil of turpentine and resin. The oil of turpentine is obtained for commercial purposes by distilling the turpentine. The resin which is left after the distillation of the oil of turpentine is the rosin of the shops. [OIL OF TURPENTINE, in ARTS AND SC. DIV.]

TURPENTINE-TREE, a name given to some of the species of trees belonging to the genus *Pistacia*. [PISTACIA.]

TURPINIA, a small genus of trees of the natural order *Celastraceæ*, named in honour of M. Turpin, a French botanical artist. *T. pomifera*, an Indian species, is called Junki-Jam in Silhet, where it bears a yellow roundish fruit of the size of a medlar.

TURQUOISE (*Calaité*, *Odontalite*), a Mineral occurring in botryoidal or mammillated masses. Colour greenish-blue, of various shades. Fracture conchoidal, rough, and uneven. Commonly opaque; sometimes translucent on the edges. Streak white. Hardness 5·0 to 6·0. Specific gravity 2·8 to 3·0. It occurs in alluvial clay in Persia. It has been found to consist of—

Phosphoric Acid	30·90
Alumina	44·50
Oxide of Copper	3·75
Oxide of Iron	1·80
Water	19·00
	—99·95

The Occidental Turquoise, found near Simon, in Lower Languedoc, is stated to be merely boue coloured by phosphate of iron. According to La Gruge, it consists of—

Phosphate of Lime	80·0
Carbonate of Lime	8·0
Phosphate of Iron	2·0
Phosphate of Magnesia	2·0
Alumina	1·5
Water	1·6
	—95·1

TURRÆA, a genus of Plants belonging to the natural order *Meliaceæ*, named in honour of an Italian botanist, G. Turra of Padua. Many of the species are highly ornamental, forming trees or shrubs in the interior of the Cape of Good Hope, in Madagascar, Mauritius, and in the eastern parts of India.

TURRILITES, De Montfort's name for a genus of Testaceous *Polythalamceæ*, occurring in a fossil state in the Cretaceous Formations. Mr. Sowerby ('Min. Conch.' vol. i. page 81) gives the generic character thus:—

Shell spiral, turreted, chambered; the turns contiguous, all visible; chambers divided by sinuous septa, pierced in their discs; aperture round.

Turrilites costatus.

As far as we know, nearly all the species are sinistrorsal; the septa have generally the sinuosities of *Ammonites*, and the siphuncle is described by Mr. Sowerby as situated near the upper (external) part of the whorls. The cavity beyond the last chamber was very large, as in *Nautilus*, and probably inclosed the greater part of the animal, so that the shell was external. The British species (*T. costatus*, *T. tuberculatus*, *T. Bergeri*, *T. undulatus*, *T. obliquus*, of 'Min. Conchology') belong to the Chalk and Greensand, and these appear to be the strata which inclose the same and other species in France and other countries.

T. costatus may be taken as an example.

TURRIS. [ACALEPHÆ.]

TURRITELLA, a genus of Gasteropodous Mollusca.

Shell turriculated, pointed, rather delicate, generally striated in the longitudinal direction of the whorls of the spire, which are numerous; aperture rounded, entire, with the edges of the lip disunited above; the outer or right lip fragile. Operculum horny, its elements concentric.

Turritella rosea.

a, Shell and animal; b, operculum. ('Astrolabe.')

Shell of *Turritella terebra*.

T. rosea, Quoy and Gaim., has the shell elongate-conical, smooth, transversely very slightly furrowed, rosy; the whorls convex; the spire acute; the aperture subquadrate.

Animal with the head elongated into a proboscideiform muzzle, brown dotted with black. The tentacles are moderately long, obtuse, white, carrying sessile eyes very near their base. The foot in elongating itself has a quadrilateral form, a little widened in front; it is greenish or yellowish, dotted with brown. The mantle has its contour fringed and sprinkled with whitish lunules, disposed in a rather regular manner.

Operculum very delicate, round, and multispiral, like that of the *Cerithia*. ('Astrolabe.')

It was found in L'Anse-de-l'Astrolabe at New Zealand, at some fathoms depth. Messrs. Quoy and Gaimard state that their dredge brought up thousands of dead individuals, among which very few living ones were found. They describe them as timid animals, seldom developing themselves like the *Cerithia*. Length 2 inches 8 lines; breadth 2 lines.

T. terebra is found in the African and Indian seas. (Lam.)

Woodward gives 50 as the number of recent species, and 150 fossil.

TURTLE. [CHELONIA.]

TURTLE-DOVE. [COLUMBIDÆ.]

TURTONIA, a genus of Conchiferous Mollusca, named by Mr. Hanley after Dr. Turton. There is but one species, *T. minuta*, which has been separated from the genus *Kellia*. The shell is oblong, inequilateral, anterior side very short; ligament concealed between the valves; hinge-teeth 2—2. Animal with the mantle open in front; foot large, keeled; siphon single, slender, elongated, protruded from the long end of the shell. It is found in Great Britain; also in Norway and Greenland. (Forbes and Hanley, *British Mollusca*.)

TURTUR. [COLUMBIDÆ.]

TUSSILA'GO (from 'tussis,' a cough), a genus of Plants belonging to the natural order *Compositæ*. It has a simple involucre, formed of a row of equal linear scales; the flowers of the head, of different sexes; the flowers of the margin, female, ligulate, entire; the flowers of the disc, hermaphrodite, tubular, 5-toothed; the stigmas linear; the receptacle naked; the pappus simple. The species are natives of Europe and America. Two are natives of Great Britain.

T. Farfara, Common Coltsfoot, has a single-flowered scape imbricated with scales, and cordate angular leaves, toothed, and downy beneath. This plant is a native of moist chalky and clayey situations throughout Europe. Its flowers come up in March and April, and have often disappeared before the leaves ascend from the ground. Dr. Sibthorp found this plant in Greece, and believes it to be identical with the Βήχιον of Dioscorides. It derives its specific name, Farfara, from its leaves resembling those of the white poplar, which was called Farfarus by the Greeks. [COLTSFOOT, in ARTS AND SC. DIV.]

TUTSAN. [HYPERICACEÆ.]

TYLOPHORA, a genus of Plants belonging to the natural order *Asclepiadaceæ*. *T. asthmatica* is very common in the peninsula of India, and called in Telinga 'kaka-palla.' Dr. Roxburgh describes it as being frequently employed there as a substitute for ipecacuanha.

TYLOS. [ISOPODA.]

TYMPANUM. [EAR.]

TYNDARIDEA. [ALGÆ.]

TYPHA. [TYPHACEÆ.]

TYPHACEÆ, *Typhads*, or *Bullrushes*, a natural order of Plants belonging to Lindley's spadicose group of Monocotyledons. The order includes two genera—*Typha* and *Sparganium*. They are herbaceous plants, growing in marshes and ditches, having stems without nodi and perennial rhizomata; the leaves are rigid, ensiform, and with parallel veins; the inflorescence is spicate or capitate, without a spathe; the flowers are unisexual; sepals 3 or more, sometimes merely a bundle of hairs; no petals; the male flowers have 3 or 6 stamens; the female flowers have a single superior 1-celled ovary; the fruit is dry, 1-celled, and 1-seeded; the embryo is in the centre of the albumen. The species of the two genera are abundant in the northern parts of the world, and are mostly absent in tropical countries.

The genus *Typha* is known by the male and female flowers being both seated on the same spike, the male flowers being uppermost; the stamens are setose, and united by the filaments; the ovary is surrounded by setæ (fig. 4); and the style is persistent. There are three species of this genus, inhabitants of the temperate parts of the globe, and all are found in Great Britain. The name *Typha* is derived from *Typos*, a 'marsh,' because these plants grow in marshy places. In English they are called Cat's-Tail and Reed-Mace, the former from the resemblance of their spikes to the tail of a cat. They are frequently called Bullrushes, but this name is restricted to another genus, the *Scirpus*.

T. latifolia, Great Cat's-Tail or Reed-Mace, has linear nearly plane leaves, with the sterile and fertile flowers continuous. This is a very handsome aquatic, and grows abundantly in damp marshy places. The leaves are three feet in length and an inch in width. When the densely crowded spike is brushed and a lighted candle applied near it, a sudden flash is produced. This arises from the firing of the pollen that is diffused in the air. On the Continent the down of the flowers is used for stuffing pillows, &c. Cattle are fond of the leaves, and the roots are sometimes eaten as a salad. In common with *Sparganium*

and *Scirpus*, the leaves are used by coopers for filling up the interstices between the wood of their casks; also for making mats, chair-bottoms,

Typha angustifolia.

1, spadix crowded with flowers; 2, stamens with united filament; 3, ditto larger; 4, ovary surrounded at the base with setae; 5, section of ovary exhibiting solitary pendulous ovule.

baskets, &c. It is this plant which many of the Italian painters have put in the hand of Christ when he was mocked by the Roman soldiers as a king.

T. angustifolia, Lesser Cat's-Tail or Reed-Mace, has linear leaves grooved below, with the sterile and fertile flowers removed at a little distance from each other. It is less frequent than the last species, but is not uncommon in the neighbourhood of London.

T. minor, Dwarf Cat's-Tail or Reed-Mace, has linear-setaceous leaves, with barren and fertile flowers at a great distance. This plant, on the authority of Dillenius, has been placed in the list of British plants. It is found in the south of Germany and Switzerland. Kock calls it *T. minima*. [SPARGANIUM.]

TYPHIS, a genus of *Mollusca*.

TYPHLOPHthalmes. [SCINCIDÆ.]

TYPHLOPS, Schneider's name for a genus of Reptiles placed by Cuvier among the Ophidians, or Serpents, and thus characterised by him:—Body covered with small imbricated scales; the muzzle advanced, furnished with plates; the tongue rather long and forked; the eye like a point, hardly visible through the skin; the vent nearly entirely at the extremity of the body; one lung four times greater than the other.

These, adds Cuvier, are small serpents similar in point of aspect to earth-worms, and species are found in the warm climates of both continents.

Some have the head of the same size as the body, and obtuse. They resemble ends of fine packthread (bouts de ficelle mince). *Typhlops braminus*, Cuv. (Russel, 'Serp. Cerom.', xlii.).

The greater part have the muzzle depressed and obtuse, furnished with many plates in front:—*Anguis reticulatus*, Scheuchzer, 'Phys. Sacr.', pl. 747.

In some the fore-part of the muzzle is covered in front with a single large plate whose anterior border is slightly trenchant:—*Anguis tumbicalis*, Lacép., ii., pl. xx.; Browne, 'Jam.', xlv. 1; 'Seb.', i., lxxvi. 2.

Finally, there is one which has the muzzle terminated by a small conic point, and is entirely blind. Its posterior extremity is enveloped in an oval and horny buckler. *T. philippinus*, Cuv., 8 inches (French) in length, and entirely blackish. ('Règne Animal')

TYPHLOPSIDÆ. [TYPHLOPS.]

TYPHLO'NIUM, a genus of Plants belonging to the natural order *Aroidæ*. The spathe is convolute at its base. Spadix interruptedly androgynous below, with rudiments of the sexual organs below the stamens, naked, with a subulate apex. Ovaries with a single ovule, affixed at the base, erect. The species are all stemless herbs, indigenous to India.

T. orizense is described by Dr. Roxburgh by the name of *Arum orizense*, and as common in the shady mango-groves near Samulkota, where the soil is dry and fertile. It is called Ghekool by the natives. Like many other of the *Aroidæ*, this plant is exceedingly acrid.

TYRANT-SHRIKES. [LANIADÆ.]

U

UARANUS. [MONITORIDÆ.]

UCA. [GECARCINUS.]

UDORA, a genus of Plants belonging to the natural order *Hydrocharidaceæ*. A probable species of this genus has been recently introduced into England, and described by Babington under the name of *Anacharis alinastrum*. The following is his description in the 'Manual of British Botany':—

It has its leaves 3 in a whorl, oval-oblong, obtuse, serrulate (the male flower is unknown), the female flower with a tubular bifid spathe, many times longer than the sessile germen: sepals, and petals, broad, nearly equal; stigmas reflexed. The stem is long, branching; whorls of leaves many and close together. Flowers subtended by a leaf-like bract placed within the whorl of leaves. Flowers very small. The sepals tinged with green and pink externally, incurved, hooded, with a narrow diaphanous margin. The petals are flat, diaphanous, recurved, and oblong. Filaments at first curved outwards, their points placed under the hood of the sepals, afterwards erect, linear, blunt, diaphanous; stigmas recurved, linear, or deeply bifid; sepals, petals, and stigmas, of about equal length; the style adnate on three sides to the tube.

This plant was first observed in Great Britain by the late Dr. Johnston of Berwick-upon-Tweed, in the river Whiteadder, in Berwickshire. It was afterwards discovered in a canal near Nottingham, and subsequently in many other places. Although at first not known, yet late inquiries have led to the conclusion that this plant is the *Udora Canadensis* of American botanists, and that it has been introduced into this country by means of the timber that is brought from the New World. Its power of retaining its vitality adapts it to bear so long a journey without destruction. The pistilliferous plants have alone been seen in Great Britain. Its power however of reproducing itself by buds is so great that it has already become a serious pest in the rivers, canals, lakes, and ponds, to which it has had access. It is one of those plants in which a circulation can be seen, and has

afforded to several observers the means of more closely watching these vegetable movements than any other plant which has yet been examined. It has been inferred by Dr. Branson and others, that the movements of the cell-contents of this plant are produced by cilia. Mr. Wenham however regards this movement as originating in the molecular activity of the proteinaceous endoplast.

(Babington, *Manual of Botany*; Marshall, *On the new Water-Weed*; Branson and Wenham, *On the Sap-Circulation of Anacharis alinastrum*, in vol. iii. of the *Quarterly Journal of Microscopical Science*.)

ULEX, a genus of Plants belonging to the section *Loteæ*, of the natural order *Leguminosæ*. The species of this genus are branched evergreen shrubs, furnished with spines, and bearing yellow flowers. The calyx is 2-parted and 5-toothed; the legume oval-oblong, turgid, scarcely longer than the calyx, containing but few seeds; ovules numerous.

U. Europæus, Furze, Gorse, or Whin, has linear-lanceolate leaves, villous branchlets, ovate loose bractæ, and a pubescent calyx. It is a common inhabitant of the plains and hills of Great Britain. It is an erect evergreen shrub with beautiful yellow flowers, which appear in greatest abundance from February to May, although in mild seasons it may be seen in blossom all the year round, giving rise to the old proverb that "Love is out of season when the furze is out of blossom." The double-flowered variety of *U. Europæus* was first found in Devonshire, and is now not uncommon in gardens and scrubberies. The double flowers add very much to the beauty of the plant. It can only be propagated by cuttings.

U. nanus, Dwarf Furze, has the teeth of the calyx lanceolate, spreading; the bractæ minute, close, pressed; the leaves linear and smooth; the branches smooth, reclining. This plant is a native of Great Britain, also of the west of France, in poor gravelly soils, but not common on the continent.

U. strictus, Irish Furze, has few or no spines, with an erect, narrow, and compact habit. This plant was discovered in the county of Down

in the Marquis of Londonderry's park. It is an upright plant, seldom flowering; its branches are soft and succulent; and in size and character it stands between the two foregoing species.

ULLMANITE. [MANGANESE.]

ULMA'CEÆ, *Elmorts*, a natural order of Exogenous Plants. The flowers are hermaphrodite or polygamous, never in catkins; calyx divided, campanulate, inferior, irregular; stamens definite, inserted into the base of the calyx, erect in aestivation; ovary superior, 2-celled; ovules solitary, pendulous; stigmas 2, distinct. Fruit 1-2-celled, indehiscent, membranous or drupaceous. Seed solitary, pendulous; albumen none, or in very small quantity; embryo straight or curved, with foliaceous cotyledons and superior radicle. (Lindley.)

Ulmus campestris.

1, branch with leaves and fruit; 2, branch with flowers before leaves are expanded; 3, ovary and stigmas; 4, embryo; 5, single flower separated.

This order consists of trees or shrubs, which have scabrous alternate simple deciduous leaves and stipules. The genera belonging to it are *Planera*, *Abelicea*, *Ulmus*, *Celtis*, *Sponia*, and *Mertensia*. The species are natives of the north of Asia, the mountains of India, of North America, China, and Europe. This order is by most botanists made a section of the natural order *Urticaceæ*. It was however separated by Mirbel, and he has been followed by Lindley. They differ from *Urticaceæ* in the possession of a 2-celled fruit and hermaphrodite flowers. In all other respects they resemble *Urticaceæ*, and their affinities are the same. [URTICACEÆ.]

Most of the species of this order are trees, the timber of which is often very valuable. The bark of the Elm is used in medicine. [ULMUS.] The genera *Planera* and *Celtis*, like the Elm, have species which are handsome ornamental trees, and yield useful timber.

ULMUS, a genus of Plants, the type of the natural order *Ulmaceæ*. The flowers are small and the leaves are alternate. In most of the species the flowers appear earlier than the leaves: they are disposed in groups, and seated on short peduncles. The calyx is of a reddish colour, distinct from the ovary, imbricated in aestivation, with 4-8 segments, which remain until the fruit falls. The stamens are as numerous as the segments, and are inserted opposite to them. The ovary is elliptical, compressed, cloven at the summit, 2-celled, and 1 ovule in each cell. The fruit is a samara, the wing-like appendage being broad and present all round, except in a notch. Only one of the cells of the ovary develops its seed, so that the fruit is 1-seeded. The embryo has no albumen, and its radicle is straight and uppermost. The leaves are stalked, and unequal at the base, serrated, and generally rough to the touch; the axils of the primary nerves beneath are tufted with fine hairy filaments. The various species of elm are wild in Europe, North America, India, and China. Nearly 20 species have been enumerated by various writers, but it is not at all certain that these are true species. This uncertainty arises from the fact which is now generally recognised by the cultivators of the elm, that the seeds of the elm do not produce plants precisely like their parents, and that the amount of difference in the elm is greater than amongst most other species of trees. It is on this account that there are so many recorded varieties of the species which are cultivated for ornament or timber.

U. campestris, the Common English or Small-Leaved Elm, has

leaves doubly serrated, rough; the flowers nearly sessile, 4-cleft; the fruit oblong, deeply cloven, glabrous. This tree is a native of the middle and south of Europe, the west of Asia, and Barbary. It is also found abundantly in France, Spain, and Italy. Although it is called the English Elm, a question has been raised as to whether it is a native of Britain; and some have supposed, on account of its not ripening its seeds in this climate, that it is an introduced plant, and that it was probably brought over by the Romans; whilst others have supposed it was brought from Palestine during the Crusades.

A great recommendation of the Elm is its endurance of a smoky atmosphere, and it will thrive in the vicinity of large towns. The noble elms of the parks of London are a living testimony of its value in this respect. Many of the public avenues in France, Holland, and Great Britain are composed entirely of this tree; and its growing in almost every variety of soil, and requiring but little pruning, are, in addition to its ornamental qualities, strong recommendations.

The recorded varieties of *U. campestris* are very numerous, and Loudon enumerates 18. Some of these have been constituted species by various botanists.

U. suberosa, the Corked-Bark Elm. This species, which derives its name from the corky nature of its bark, is supposed by Selby and others to be only a variety of *U. campestris*.

U. major, the Greater or Dutch Corked-Bark Elm, is considered a species by Smith, and recognised by Lindley and Hooker. It has rough ovate-acuminate leaves, very oblique at the base, sharply and doubly serrated, pubescent below, with dense tufts of white hairs in the axils; branches spreading, bright brown, winged with corky excrescences, when young nearly smooth; fruit obovate, slightly cloven, naked. This is a finer and more graceful-looking tree than the last. It has larger leaves, and the bark is even more corky.

U. effusa, the Spreading-Elm. This is not a British species. It has doubly serrated leaves, unequal at the base; pedunculated pendulous flowers, with the margin of the fruit (samara) ciliated. This tree is a native of Russia, where it attains a great size.

U. montana, the Mountain, Scotch, or Wych Elm. It has obovate, cuspidate, doubly and coarsely serrated leaves, nearly equal at the base, exceedingly scabrous above and downy beneath, bark smooth; fruit scarcely cloven, naked. Whatever may be the doubts as to the introduction of the *U. campestris* into Britain, there are none with regard to this species, which is always allowed to be British. The leaves of the Wych-Elm are larger than those of the English Elm.

U. glabra, the Smooth-Leaved Elm, is sometimes considered a variety of the last species. The leaves are ovate-lanceolate, acuminate, doubly and evenly crenato-serrate, cuneate and oblique at the base, quite smooth above, smooth or glandular beneath, with a few hairs in the axils; branches bright-brown, smooth, wiry, weeping; fruit obovate, naked, deeply cloven. This tree is a native of Britain, occurring in the greatest abundance in the county of Essex.

U. Americana, the American Elm. The petiole of the leaf is 1-1½ inch in length, covered with short hairs; the disc unequal at the base, 4 or 5 inches long, serrated, and mostly doubly so; axils of the veins joined by a membrane; the flowers are seated on peduncles, the peduncles short, glabrous; the stamens 5 to 8; the fruit ovate, acute, ciliated. Its flowers resemble those of *U. effusa*. This tree is found in North America, growing in low woods from New England to the Carolinas, where it attains a height of from 80 to 100 feet.

U. fulva, the Slippery Elm, has rough whitish branches; ovate-oblong acuminate leaves, nearly equal at the base, serrate with unequal teeth, very rough and hairy on both surfaces; the leaf-buds tomentose, scales of flower-buds downy; fruit not ciliated. This tree is also a native of North America.

U. alata, the Wahoo, or Cork-Winged Elm, is another American species. It is a small tree, seldom exceeding 30 feet in height, and is characterised by the bark dilating on each side of the branches between the leaves, and giving them a winged appearance. [ELM, in ARTS AND SC. DIV.]

ULNA. [SKELETON.]

ULODENDRON. [COAL-PLANTS.]

ULTIMUS. [CYPRIDEÆ.]

ULTRAMARINE. [LAZULITE.]

ULULA. [STRIGIDÆ.]

ULULINÆ. [STRIGIDÆ.]

ULVA. [ALGÆ.]

ULVACEÆ. [ALGÆ.]

UMBEL, a form of inflorescence in Plants, characteristic of the natural order *Umbelliferae*. [INFLORESCENCE; UMBELLIFERÆ.]

UMBELLIFERÆ, a natural order of Exogenous Plants. This is one of the best marked families of plants, so much so, that Jussieu says the whole order may be looked upon as a genus, and the various subdivisions and genera as arrangements of the species. All the species are well marked, and have good distinguishing characters, and their inflorescence is always that of the umbel. The possession of an umbel was early made the combining character of these plants by systematic botanists, and they were called *Umbellatæ* on this account. In addition to this distinguishing character, they have also others, as the possession of 5 stamens and 2 stigmas, by which they were all brought under the class *Pentandria* and order *Digynia* of Linnæus.

Most of the species are herbs, seldom shrubs, with fistular furrowed

stems. The leaves are, in most cases, divided; sometimes they are simple; they are alternate, and all of them embrace or clasp the stem by a sheathing petiole. The flowers are white, pink, yellow, or blue, and are seated on umbels, which are either simple or compound, and these are with or without bracts at their base, which are called involucre, or involucrellum, as they surround the umbels, or umbellules. The calyx is superior, either entire or 5-toothed. The petals are 5, and are inserted on the outside of a fleshy disc, which is placed on the top of the ovary; they are usually inflexed at the point, and have an imbricate, rarely valvate aestivation. The stamens are 5, and are seated alternately with the petals, and are incurved during aestivation. The ovary is inferior, 2-celled, having solitary pendulous ovules, and is crowned by the disc, on which the petals are seated; the styles are two, distinct, with simple stigmas. The fruit, which is ordinarily called the seed, consists of 2 carpels, which are united by a common axis, the part by which they unite being called the commissure; the external part of each carpel is traversed by elevated ridges, which are divided into primary and secondary; there are 5 of the latter, and 4, between them, of the former; the ridges are separated by channels, below which are often placed, in the covering of the fruit, little receptacles of coloured oily matter, which are called vittæ. The seed, which is pendulous, usually adheres to the sides of the cell of the fruit, and this has led to the confounding the seed and fruit together. The embryo is minute, and is seated in the midst of a horny albumen, with the radicle pointing to the hilum.

Hydrocotyle Spananthe.

1, cutting, showing umbels with flowers and fruit; 2, flower enlarged; 3, fruit; 4, transverse section of fruit; 5, seed removed from pericarp, with small embryo and large albumen.

The order agrees with *Ranunculaceæ* in its sheathing leaves, as well as its large albumen and its acrid properties. Other relations have been pointed out, as with *Saxifragaceæ*, *Geraniaceæ*, also with *Araliaceæ*, from which it differs little, except in the number of the parts of the flower.

The following conspectus will show the sub-orders and tribes into which numerous genera of this order have been distributed by De Candolle:—

Umbelliferae.	<i>Hydrocotyleæ.</i>	
	<i>Mulinææ.</i>	
	<i>Saniculææ.</i>	
	<i>Amminææ.</i>	
	<i>Seselinææ.</i>	
	<i>Angeliceæ.</i>	
	<i>Peucedaneæ.</i>	
	<i>Tordyliææ.</i>	
	<i>Sileneææ.</i>	
	<i>Oumineææ.</i>	
Sub-Order I. <i>Orthospermeæ</i> .—Albumen of seed flat on inner surface, neither involute nor convolute.	<i>Thapsiææ.</i>	
	<i>Daucineææ.</i>	
	<i>Elæoselinææ.</i>	
	<i>Caucalinææ.</i>	
Sub-Order II. <i>Campylospermeæ</i> .—Albumen rolled inwards at the edges	<i>Scandiacineææ.</i>	
	<i>Smyrniææ.</i>	
	<i>Coriandreeæ.</i>	
Sub-Order III. <i>Cetiospermeæ</i> .—Albumen curved inwards from base to apex.		

Tausch has more recently proposed another arrangement, and objected to the albumen being made the basis of the primary divisions of the order.

The genera include above 1060 species. These are principally inhabitants of the northern temperate zone, and the greater number of them are found in the Old World. The proportion of species in the southern half of the world, compared with the northern, is as one to four; that of the New to the Old World, as one to three. Very few of the species are found in the tropics, and about 50 are enumerated as inhabitants of Australia.

The properties of this order are variable, and very important. One of the distinguishing characters of the order is the possession of an acrid principle which finds its full development in such plants as the Hemlock [*Conium*], the Cow-Bane [*Cicuta*], *Eranthe*, *Helosciadium*, *Aithusa*, &c. This renders the whole order suspicious, more especially the vegetation, in which the poisonous principle is most developed. The acrid properties of these plants seem to depend upon the possession of a peculiar principle, which in as far as it has been examined in some of the species possesses alkaline properties. This is the case with Conia, a principle obtained from the Hemlock [*Conium*], which has been examined with the most care, although other plants of the order have been found to yield similar principles, but not possessing so much activity. Conia is remarkable amongst the vegetable alkaloids, for being fluid, volatile, and easily decomposed; and it is probable that most plants whose poisonous properties are dissipated by heat possess a principle of a similar nature. In this respect there is also another analogy between the *Umbelliferae* and *Ranunculaceæ*, the poisonous qualities of the species of the last order being in a great measure annihilated by heat. It is not improbable that all the *Umbelliferae* may possess a principle similar in nature, though not in intensity, to the Conia, and that it may contribute in some measure to render such plants as the parsley, samphire, and celery, desirable as articles of diet.

Another important secretion of the *Umbelliferae* is a volatile oil. This secretion is found in all the species, with the exception of *Conium*, deposited in the canals of the pericarp, which are called vittæ. In some of the species it is more abundant than in others; and on this account the fruit, which is commonly called the seeds, is used frequently in diet as a condiment, and in medicine as an aromatic and carminative. Of these the carraway, the anise, the dill, the cumin, and coriander are best known.

A third secretion of these plants is a gum-resin. This probably, like the last two secretions, is common to the whole order, but is fully developed in only a few species. The gum-resins produced by this order have had a great reputation in medicine, and many of them are still looked on as valuable remedies. The Laser, or Silphion, of the ancients, is secreted by plants belonging to this order, and asafoetida, galbanum, gum-ammoniacum, opoponax, and sagapenum are much used as stimulant medicines in nervous diseases at the present day. Many of the species when wounded exude in small quantities a gum-resinous matter.

A fourth secretion, which also on account of its occasional excess renders this order important to man, is starch. This secretion, which forms so large a portion of the food of animals, is deposited in largest quantities in the roots of the carrot, the parsnip, the skirret, and the amaccha of the South Americans, and on this account these plants are extensively cultivated. Most of the roots however contain this principle, and might be used as articles of diet, but they also contain the poisonous principle of which we have before spoken. Heat will dissipate this, and some of the roots which are deadly poisonous when raw, it is said may be eaten with impunity when cooked. The roots of some of these plants resemble that of the horse-radish, and in winter, when the leaves are gone, may be dug up in mistake for it. Fatal consequences have in some cases ensued from such a mistake. Many of the *Umbelliferae* are much affected in their secretions by climate and cultivation. Thus, the deadly hemlock in Russia is an inert and eatable plant, while the celery of our gardens, if cast on the roadside, becomes an active poison. The properties of all plants are more or less affected by climate and cultivation; but it is much more obvious where poisonous secretions are increased or diminished, as in the hemlock, or changed, as in the case of the celery.

(Jussieu, *Dict. des Sciences Naturelles*; Lindley, *Vegetable Kingdom*; Don; Miller, *Dictionary*; Burnett, *Outlines*; Christison, *Dispensatory*; Bischoff, *Lehrbuch der Botanik*.)

UMBELLUS. [BONASIA.]

UMBER (Ornithology), a name of the *Scopus umbretta*, *Ombretta* of the French, a bird belonging to the family *Ardeidae*.

Scopus is distinguished from the *Storks* by its compressed bill whose trenchant culmen is expanded towards the base: the nostrils are prolonged into a furrow which runs parallel to the culmen to the end, which is slightly hooked.

Bill of *Scopus*.

S. umbretta is the size of a crow, colour that of umber; the male with an occipital crest. It is found generally in Africa.

Scopus umbretta.

UMBER, an Ore of Iron and Manganese, employed as a brown pigment. It occurs massive, amorphous. Structure earthy. Fracture conchoidal. Soft. Opaque. Dull. Meagre to the touch; adheres strongly to the tongue, and falls to pieces in water. Colour blackish, reddish, or yellowish-brown. Specific gravity 2.206. It occurs in beds with brown jasper, in the Isle of Cyprus. It consists of iron, manganese, silica, alumina, and water.

UMBILICUS. When the inner sides of the whorls or volutions of a spiral shell do not touch each other, so that its axis is hollow, that hollow is termed the Umbilicus. [TROCHIDÆ; TURBINIDÆ.]

UMBILICUS, a genus of Plants belonging to the natural order *Crassulaceæ*. It has a 5-parted calyx; corolla gamopetalous, campanulate, 5-cleft; lobes ovate, acute, erect, about the length of the tube; stamens 10, inserted in the corolla; scales 5, obtuse; carpels 5, attenuated at the apex; styles subulate. The species are herbs, indigenous to the south of Europe and the Levant. The leaves are rosulate or alternate, quite entire, or a little toothed. The flowers white or yellow, in branched or simple terminal racemes, never in cymes. There are about 17 species. They grow chiefly on rock-work and on old walls. *U. spinosus* and *U. leucantha* are natives of Siberia. Some of the species are British, and still remain in the old genus *Cotyledon*, out of which the genus *Umbilicus* has been formed. *U. erectus* is the *Cotyledon Umbilicus* of Linnæus, and is described under that genus. [COTYLEDON.]

UMBO (Conchology), the name for that point in a conchifer or bivalve shell which constitutes the nucleus or apex of each valve, and which is generally situated above the hinge, and always near it. [CONCHIFERA.]

UMBRELLA. [SEMIPHYLLIDIA.]

UNAU (*Cholepus*), a genus of Edentate Animals inhabiting America. The position of this animal with the other forms of the Tardigrade Edentata will be seen in the following conspectus [BRADYPUS], drawn up by Professor Owen, and published in his work on the 'Osteology, Natural Affinities, and probable Habits of the Megatheroid Quadrupeds in general':—

Conspectus of the Families, Genera, and Species of the
Leaf-Eating Bruta.

Order Bruta, Linn., Fisch. (*Edentata*, Cuv.).

Teeth none, or wanting a neck and enamel. Claws falcate, great, generally sheathed, bending downwards.

Tribe Phyllophaga (Leaf-Eaters).

Teeth few, composed of vascular dentine, hard dentine, and cement; the vascular dentine forming the great axis of the teeth. A descending apophysis in the jugal bone. The acromion concretes with the coracoid process.

Family I. *Tardigrada* (Syn. *Scansoria*, *Bradypodidae*).—Feet long, slender, the anterior more or less longer than the posterior; fore feet di- or tri-dactyle, hind feet tridactyle; toes obovate, falcate. Zygomatic arch open. Tail very short.

Genus 1. *Bradypus*, Linn., Ill. (*Acheus*, F. Cuv.).

Genus 2. *Cholepus*, Ill. (*Bradypus*, F. Cuv.).

Family II. *Gravigrada* (*Eradicatoria*, *Megatheriidae*).—Feet short, very strong, equal or subequal; fore feet penta- or tetra-dactyle; one or two of the external toes unarmed, fit for support and progression; the rest falcate. Zygomatic arch closed. Clavicles perfect. Tail moderate, stout, and acting as a fulcrum or prop.

Genus 1. *Megalonyx*, Jefferson, Cuv. (*Megatherium*, Desm., Fisch.).

Teeth $\frac{5-5}{4-4}$, subelliptical, the middle of the crown excavated, the margins slightly prominent. Fore legs the longest; the tibia and fibula distinct; the heel-bone long, compressed, and deep; the falcular claws great and compressed.

Species, *M. Jeffersoni*, Cuv. (*Megatherium Jeffersoni*, Desm., Fisch.; *Megalonyx laqueatus*, Harlan).

Genus 2. *Megatherium*, Cuv. (*Bradypus*, Pander and D'Altou).—

Teeth $\frac{5-5}{4-4}$, contiguous, tetragonal, the crown transversely sulcated. The fore feet tetradactyle; the hind feet tridactyle, the two external toes unarmed; the falcular claws great and diversiform; those of the middle toe greatest, and compressed. Femur with an entire (unimpressed) head; tibia concrete, with the fibula at each extremity. Astragalus with the anterior face excavated above. Heel-bone long and thick.

Species, *M. Cuvieri*, Desm. (*Bradypus giganteus*, Pander and D'Altou).

Genus 3. *Myiodon*, Owen (*Megalonyx*, Harlan; *Orycterotherium*, Harlan).—Teeth $\frac{5-5}{4-4}$, distinct; the anterior upper tooth subelliptical,

moderately remote from the rest; the second elliptical; the rest trigonal, with the internal face longitudinally sulcated; the anterior lower tooth elliptical, the penultimate tetragonal; the last, which is the greatest, bilobate. Feet equal: fore feet pentadactyle; hind feet tetradactyle; the two external toes in both unarmed, the rest falcate; the falcular claws great, semiconical, and unequal. Head of the femur impressed by the round ligament; tibia and fibula distinct; astragalus with anterior face flattened above; heel-bone long and thick.

Species 1, *M. Darwinii*, Owen. The lower jaw with the symphysis longer and narrower; the second molar subelliptical; the last bisulcate, the internal furrow angular.

Species 2, *M. Harlani*, Owen (*Megalonyx laqueatus*, Harlan; *Orycterotherium Missouriense*, Harlan). Lower jaw with a shorter and wider symphysis; second molar subquadrate; the last trisulcate, the internal furrow biangular.

Species 3, *M. robustus*, Owen. Lower jaw with the symphysis shorter and wider; second molar subtrigonal; the last trisulcate, the internal furrow rounded.

Genus 4. *Scelidotherium*, Owen (*Megalonyx*, Lund).—Teeth $\frac{5-5}{4-4}$, either contiguous or separated by equal intervals; upper ones trigonal; the anterior of the lower ones trigonal, the second and third subcompressed, the external face longitudinally sulcated; the last the greatest and bilobate. Head of the femur impressed by the ligamentum teres; tibia and fibula distinct; astragalus with two excavations anteriorly. Heel-bone long, thick; falcular claw great and semiconical.

Unau (*Cholepus*). (De Blainville.)

Species, *S. leptcephalum*, Owen; *S. Cuvieri*, Owen (*M. Cuvieri*, Lund); *S. Bucklandi*, Owen (*M. Bucklandi*, Lund); *S. minutum*, Owen (*M. minutus*, Lund).

Genus 5. *Catodon*, Lund.—Teeth $\frac{4-4}{3-3}$.

Genus 6. *Sphenodon*, Lund.

In the Unau the number of cervical vertebrae is 7; in the Three-Toed Sloth (*Bradypus tridactylus*) the number is 9.

Cervus [CERVIDÆ], *Capra* [CAPRÆ], *Ovis* [OVIDÆ], and *Bos* [BOVIDÆ]. [MAMMALOGY.]

Mylodon robustus.

UNCARIA, a genus of Plants belonging to the natural order Rubiaceæ. *Uncaria* is sometimes considered only as a sub-genus of *Nauclea*. The flowers are aggregate, on a globular receptacle; calyx tubularly urceolate, 5-cleft; corolla funnel-shaped, with a slender tube and naked throat; stamens 5; ovary 2-celled; capsules pedicellate, clavate, attenuated at the base; seeds imbricated, winged; embryo inverse and furnished with a perisperm. The species are chiefly natives of India, but a few are found in America. They are permanent cirrhiferous ramblers, hanging to different trees by the hooked old peduncles.

U. Gambier, Roxburgh, the Gambier Plant, is a native of Penang, Sumatra, Malacca, &c. The substance called Gambier by the Malays is prepared from it, and it is known in commerce by the names of *Terra japonica* and *Catechu*.

This plant was first described by Rumphius, 'Herb. Amb.', v., p. 63, t. 34, f. 2 and 3, by the name of *Funis uncatus angustifolius*, but the process of preparing the extract was first fully described by Dr. C. Campbell, one of the early medical officers of the station of Bencool, who paid considerable attention to the useful plants of the neighbourhood. He states that it is chewed by the Malays mingled with betel-leaf and areca nut in the same way that catechu is used on the continent of India, and was solicitous that a trial should be made of its power in tanning. The preparation he describes as simple:—"The young shoot and leaves are shired and bruised in water for some hours, until a feculum is deposited: this, inspissated in the sun to the consistence of a paste, is thrown into moulds of a circular form, and in this state the gambier is brought to market." [CATECHU, in ARTS and SC. DIV.]

UNCITES, a fossil genus of *Brachiopoda*.

UNGKA-ETAM, the Asiatic name for *Hylobates Roffesii*, Geoffroy. [HYLOBATES.]

UNGKA-PUTI, an Asiatic name for *Hylobates agilis*. [HYLOBATES.]

UNGUICULATA. Linnæus divided the Mammalia into the following sections:—*Unguiculata*, *Ungulata*, and *Mutica*.

The *Unguiculata*, or Clawed Mammals, included the orders *Bruta*, *Glires*, *Primates*, and *Fera*.

UNGULATA, Hoofed Mammals. Under this section Linnæus included the orders *Bellua* and *Pecora*.

The *Bellua* comprised the genera *Equus* [EQUIDÆ], *Hippopotamus*, *Sus* [SUIDÆ], and *Rhinoceros*.

The *Pecora* consisted of the genera *Camelus*, *Moschus* [MOSCHIDÆ],

UNGULINA. [LITHOPHAGIDÆ.]

UNICORN. [RHINOCEROS.]

UNIO. [NAIADÆ; UNIONIDÆ.]

UNIONIDÆ. Mr. Swainson makes the *Unionida* the first family of his third tribe (*Atrachia*) of his order '*Dithyra*, Bivalve Shells,' and thus defines and arranges it:—

Unionida, River Mussels, or Unios.—Animal fluviatile; shell solid, perlaceous; generally with cardinal and lateral teeth.

Sub-Family 1. *Unionina*.—One valve, with two cardinal and two lateral teeth; cardinal teeth short; the umbones, or bosses, smooth or longitudinally undulated.

Genera:—*Unio*, Lam. (with the sub-genera *Unio*, *Cunicula*, Sw., *Ligumia*, Sw., *Theliderma*, Sw., and *Megidomus*, Sw.).

Eglia, Sw. (with the sub-genera *Eglia*, *Naidea*, Sw., and *Cathyrina*, Sw.).

Mysea, Turton (with the sub-genera *Potumida*, Sw., and *Lymnaea*, Sw.).

Sub-Family 2. *Hyriana*.—Bosses longitudinally sulcated; cardinal teeth long, compressed, placed on one side of the bosses; hinge-margin winged.

Genera:—*Iridea*, Sw.; *Castalia*, Lam. (with the sub-genera *Naia*, Sw., and *Castalia*, Lam.); *Hyria*, Lam.; *Hyridella*, Sw.

Sub-Family 3. *Iridinina*.—Narrow and greatly elongated; hinge margin without teeth, but sometimes granulated.

Genera:—*Iridina*, Lam.; *Callicapha*, Sw.; *Mycetopus*, D'Orb.

Sub-Family 4. *Anodontina*.—Cardinal teeth none; lateral tooth extending along the hinge or entirely wanting; hinge-margin generally winged.

Sub-Genera:—*Lamproscapha*, Sw.; *Symphynota*, Lea; *Anodon*, Lam.; *Hemiodon*, Sw.; and *Patularia*, Sw.

Sub-Family 5. *Alasmodontina*.—Lateral teeth entirely wanting; cardinal teeth one or two.

Genera:—*Calceola*, Sw.; *Alasmodon*, Say (with the sub-genera *Unioopsis*, Sw., *Margaritana*, Schum., and *Complanaria*, Sw.). ('Malacology.')

Dr. J. E. Gray makes the *Unionida* the eighth family of his order *Cladopoda*.

Genera:—*Anodon*, *Margaritana*, *Alasmodon*, *Damaria*, *Unio*, *Heterodon*, *Dipsas*, and *Monocondyla*.

The *Iridinidæ* form the ninth family of the same order in Dr. Gray's arrangement.

Genera:—*Iridina*, *Leila*, *Pleiodon*, *Hyria*, *Castalia*. ('Sycopsis Brit. Mus.')[NALADE.]

UNONA, a genus belonging to the natural order *Anonaceæ*, so called from 'unus,' one, the stamens being united with the germens. The generic character is, sepals 3; petals 6, the 3 inner the smallest; stamens numerous; carpels numerous, one- or many-celled; many-seeded, seeds in a single row. The species consist of trees, large shrubs, or climbing plants, found in hot parts of the world, as India and its islands, Africa, and South America. The bark and fruit of many of the species are aromatic, with some degree of acridity, and are employed as stimulating medicines or as condiments.

U. Ethiopica, a native of Ethiopia and Sierra Leone, is a tree with ovate-lanceolate leaves, which are also acute, smooth, and have the under surface glaucous; it has roundish, torulose, nearly sessile carpels. It has obtained more celebrity than other species, from being supposed to be that which yields the seeds formerly well known under the name of Ethiopic pepper, the 'Filfilal-Soudan' of Arabian authors. They have been also called Guinea Pepper and Negro Pepper, in consequence of their having been employed as a substitute for that condiment by the negroes, from their aromatic and pungent taste. They must not be confounded with the *Amomum Granum Paradisi*, obtained also from the west coast of Africa.

U. aromatica, another species, which is a native of or introduced by the negroes into Guyana, is however considered by some to be the species yielding the Negro Pepper. It has oblong, acuminate, and smooth leaves; peduncles axillary, 1-2-flowered; carpels oblong, terete, torulose, nearly sessile. Every part of the plant is aromatic, and the fruit is used as a condiment by the negroes of Guyana.

U. undulata, a native of Waree in Guinea, has aromatic fruit similarly employed.

U. Narum is one of the climbing species, a native of Malabar, which Rheede describes as possessed of medicinal properties, the roots being so used, as well as the sweet-scented greenish-coloured oil obtained from them by distillation.

U. musaria has been so called from its bark being used for making musical instruments, as is indeed also that of the foregoing species. This is a rambling shrub, a native of Amboyna, &c., the roots and bark are also used medicinally. *U. tripetala*, *U. uncinata*, *U. odorata*, &c., natives of the Indian islands, are remarkable for the sweet scent of their flowers. *U. esculenta*, a native of the Indian peninsula, has fruit which is edible. Some species, as *U. sylvatica*, are valued for their timber. *U. longifolia* is an elegant tree, with smooth, pointed, and undulate leaves, which is much cultivated in some parts of India to form avenues and to afford shade. It is sometimes called Deodara, which is properly the name of the celebrated Himalayan Pine, *Pinus* or *Cedrus Deodara*.

UPAS TREE. [ANTIARIS; STRYCHNOS.]

UPUPA. [UPUPIDÆ.]

UPUPIDÆ, a family of Insessorial or Perching Birds.

Linnaeus placed the genus *Upupa* between *Merops* and *Certhia* [CERTHIDÆ], among his *Picæ*, in his last edition of the 'Systema Nature'; the species of *Upupa* recorded by him are *U. epops*, *U. promerops*, and *U. paradisea*.

Mr. G. R. Gray makes the *Upupidæ* (*Upupa*, Linn.), the first family of the *Tenuirostres*, consist of the following sub-families and genera:—

Sub-Family 1. *Upupina*.

Genera:—*Upupa*, Linn.; *Fregilupus*, Less.; *Falculia*, J. Geoffr.; *Neomorpha*, Gould; *Selucides*, Less.; *Craspedophora*, G. R. Gray; *Ptiloris*, Sw.

Sub-Family 2. *Promeropina*.

Genera:—*Promerops*, Brissou; *Rhinopomastus*, Smith; *Epinachus*, Cuvier.

The *Upupidæ*, in Mr. Gray's arrangement, are immediately succeeded by the *Nectarinidæ*.

Our limits will not permit us to notice particularly in this article more than the genera *Upupa*, *Promerops*, and *Epinachus*.

Upupa, Linn.—Bill very long, slightly arched, slender, triangular, compressed; nostrils basal, lateral, ovoid, open, surmounted by the feathers of the forehead; feet with three anterior toes, the external joined to the middle toe up to its first joint; one posterior toe; claws short and slightly curved, that of the hind toe nearly straight; tail squared, composed of ten feathers; wings moderate, fourth and fifth quills the longest; tongue very short, triquetral.

U. epops, the Hoopoe. This is the 'Ερως of the Greeks (Aristotle, 'Hist. Anim.,' i. 1; ix. 11; ix. 15, 49; Aristophanes, 'Birds,' 223, et seq.; Pausanias, x. 4); *Upupa* and *Epops* of the Romans (Pliny, 'Nat. Hist.,' x. 29; xxx. 6; Ovid, 'Metam.,' vi.). In Ovid's lines descriptive of the transformation of Tereus, the bird is drawn to the life:—

"Tereus

Vertitur in volucrem, cui stant in vertice crista.
Prominet immoedicum pro longa cuspidē rostrum,
Nomen Epops volueri, facies armata videtur."

"Tereus, through grief, and haste to be reveng'd,
Shares the like fate, and to a bird is chang'd.
Fix'd on his head the crested plumes appear,
Long is his beak, and sharpen'd as a spear."—Crozall.

It is the Buba, Upega, Gallo del Paradiso, Galletto de Magio, Pubula, Bubbola, Pupita, and Upupa, of the Italians; Hupe, Huppe, Putput, Huput, and Lupoge, of the French; El Abubilla of the Spanish; Wiedehopf of the Germans; De Hopps of the Netherlanders; Ilazfogel of the Swedes; Her-fugl of the Danes; Smerda Kaura of Scopol; Dung-Bird of the English; Y Goppog of the Welsh.

Two parallel rows of long feathers form an arched crest upon the head; these feathers are of a ruddy buff colour, terminated with black;

Bill of Hoopoe.

head, neck, and breast, vinous buff; upper part of the back vinous gray; on the back a large transversal band; wings and tail black; on the wings are five transversal bands of yellowish-white, and on the tail is a very large white band, about the middle of the feathers; at about three-fourths of the length of the quills is a large white band; abdomen white, with some longitudinal spots on the thighs; bills flesh-colour at its base, and black towards the point; feet and iris brown. Length, 12½ inches.

The female is less than the male, her crest shorter, and the tints of her plumage less vivid.

The young when they leave the nest have the bill short, nearly straight, and slightly cylindrical towards the point; the feathers of the crest short and often terminated with black, without the white spot which is immediately below it in the adult; the white band of the tail nearer to the rump; the plumage washed, as it were, with ash-colour; the bands on the wings less distinct and more yellowish, and a greater quantity of longitudinal spots upon the belly and thighs.

This bird is found as far north in the summer as Denmark, Sweden, and Russia; and southward in continental Europe, in Germany, Holland, France, Spain, and Italy. It has been seen both at Gibraltar, Ceuta, and in Egypt (where it breeds); it is probably an inhabitant of the whole of North Africa. It has been also observed at Madeira, and at Trebizond, in Asia Minor, from which last locality it has been sent to this country.

It is generally found in the British Islands in autumn, but Hoopoes have been known to build and hatch their young with us. The flesh of the bird in autumn is said to be well flavoured.

Hoopoe (*Upupa epops*).

Mr. Yarrell has recorded the manners of a Hoopoe in the possession of Mr. Bartlett, a preserver of birds in Museum-street, London. "This bird," says Mr. Yarrell, "is quite tame, and when unexcited the high crest falls flat over the top of the head and covers the occiput; it takes a meal-worm from the hand very readily, nibbles and pinches it between the ends of the mandibles, then putting it on the ground, strikes it several blows with the point of the beak; when the insect is apparently dead or disabled it is again taken up, and by a particular motion of the head, which is thrown backward, and the beak opened, the meal-worm drops into the gape of the mouth and is swallowed. The call for another is a sharp note; but it also utters at times a sound closely resembling the word 'hoop, hoop, hoop,' but breathed out so softly, but rapidly, as to remind the hearer of the note of the Dove. This bird constantly rubs himself in the sand with which the bottom of his large cage is supplied, dusting himself like the larks, but takes great care to shake off any sand or gravel that may adhere to his food, which is raw meat chopped and boiled egg.

"At the moment of settling on the floor of the room, Mr. Bartlett's bird bends the head downwards till the point of the beak touches the floor, after which, as well as occasionally at other times, the long feathers forming the crest are alternately elevated and depressed in a slow and graceful manner, the bird assuming an appearance of great vivacity, running on the ground with a very quick step. M. Necker, in his 'Memoir on the Birds of Geneva,' says Hoopoes fight desperately, and leave the ground covered with their feathers." ('British Birds.')

Promerops, Briss.—Bill with the under mandible, at its base, thicker than the upper; the margin acute; nostrils corneous; the aperture lateral and oval; hind claw curved; tail long, cuneated. (Sw.)

P. erythrorhynchus (*Upupa erythrorhynchus*, Lath.). The whole plumage varying with metallic blue and green; the bill coral-red.

Promerops erythrorhynchus.

This brilliant bird, the *Promerops* Moqueur of the French, lives in small troops in South Africa (interior of the Cape of Good Hope). It is said that there is a variety from Senegal, which has two large white stripes on the wings and on the external tail-feathers.

Epimachus, Cuv. Bill resembling that of *Promerops*, but the margins are obtuse and somewhat inflected; wings, tongue, and feet unknown; tail very long; side-feathers of the body greatly developed.

E. magnus (*Upupa magna*, Gm., *U. superba*, Lath.). Body generally black or brownish-black; tail graduated, thrice as long as the body (Lesson says three feet in length, French); feathers of the sides elongated, raised, curled, glittering on their edges with steel-blue, azure, and emerald-green, like precious stones; the head and the belly lustrous also with steel-blue, &c. In truth, language fails to convey any just idea of the magnificence of this species. It inhabits the coasts of New Guinea.

Grand *Promerops* (*Epimachus magnus*).

UITA'NIA, a genus of Plants belonging to the natural order *Musaceæ*. The name which the plant bears in Madagascar is *Ravenala*. This genus has but one species, *U. speciosa*, which is a native of Madagascar. It has a superior coloured perianth, consisting of 3 petals; a 2-leaved nectary, and one of the leaves bifid; a 3-celled many-seeded capsule, and the seeds in two rows covered with an aril. The flowers are arranged upon a spadix, which are nodding, very similar to the bananas, which belong to the same family. The leaves are arranged in a fan-shape. The seeds of this plant are said to constitute a wholesome food.

URANISCODON. [IGUANIDÆ]

URANITE. [URANIUM.]

URANIUM, a Metal discovered by Klaproth, in 1789, who named it after the planet Uranus, the discovery of which had previously occurred in the same year: the mineral from which it was first obtained is called *Pechblende*, in German.

Pitchblende, or *Oxide of Uranium*.—This Mineral occurs in amorphous and reniform masses, and also pulverulent. Structure granular, compact. Fracture uneven, conchoidal. Hardness: scratches phosphate of lime, is scratched by felspar. Colour grayish, brownish, and iron-black. Opaque. Lustre imperfect metallic. Specific gravity 6.463. Before the blow-pipe infusible per se, but colours the exterior flame green; with borax it fuses into a dull-yellow glass, which becomes green in the reducing flame. In powder, it dissolves slowly in nitric acid. Pitchblende occurs in Saxony, Bohemia, &c., and in Cornwall. The following analyses are by Klaproth and L'faff.

	Klaproth.	Pfaff.
Oxide of Uranium	86.5	84.52
Oxide of Iron	2.5	8.24
Silica	5.0	2.02
Sulphuret of Lead	6.0	4.20
Oxide of Cobalt	—	1.42
	100	100.4

This mineral is evidently a mere mixture of Oxide of Uranium, with other substances, and, besides those above enumerated, Arfwedson found the oxides of arsenic, zinc, and copper, in the Pitchblende of Joachimsthal.

Chalcolite, Green Uranite, Cupreo-Phosphate of Uranium.—This Mineral agrees with the preceding in crystalline form, but differs in colour, it being grass- or emerald-green, owing to the presence of phosphate of copper instead of phosphate of lime. It occurs in Cornwall, was first shown to contain uranium by the Rev. Mr. Gregor, and analysed afterwards by R. Phillips and subsequently by Berzelius; the results of the experiments gave as its composition—

	Phillips.	Berzelius.
Phosphoric Acid	16.0	15.56
Oxide of Uranium	60.0	60.25
Oxide of Copper	9.0	8.44
Water	14.5	15.05
Stony Matter	0.5	0.70
	100	100

Uranite, Uran-Mica, Calcereo-Phosphate of Uranium occurs crystallised. Primary form a square prism. Cleavage parallel to the terminal planes, very distinct. Fracture foliated. Hardness: scratches sulphate of lime, and is scratched by the carbonate. Colour lemon- or golden-yellow, and yellowish-brown. Lustre adamantine. Transparent, translucent. Specific gravity 3.12 to 3.33. It is found in veins in granite at St. Symphorien near Autun, and at St. Yrieux near Limoges in France, and also in several places in Saxony. An analysis of a specimen from Autun by Berzelius gave:—

Phosphoric Acid	14.63
Oxide of Uranium	59.37
Lime	5.66
Silica and Oxide of Iron	2.85
Magnesia and Oxide of Manganese	0.19
Barytes	1.51
Water	14.90
Fluoric Acid and Ammonia	Traces
	—99.11

This mineral appears essentially to consist of the phosphates of uranium and lime.

Carbonate of Uranium, Uran-Bloom, Uraconite, occurs in small indistinctly crystalline flakes. Lustre but slight. Colour bright-yellow. Occurs in silver-veins at Joachimsthal in Bohemia, forming a coating on pitchblende.

Sulphate of Uranium.—This occurs as a thin botryoidal yellow-coloured coating over the surface of the minerals on which it is found. It is friable, and soils the fingers. Partially soluble in water, and the remainder in nitric acid; both solutions contain sulphate of uranium, and are of a yellow colour. It is found at Joachimsthal in Bohemia.

Sulphate of Uranium and Copper, Johannite, occurs crystallised. Primary form an oblique rhombic prism. Crystals very minute. Fracture imperfect conchoidal. Hardness 2 to 2.5. Taste slightly bitter. Partially soluble in water. Colour deep grass-green. Streak paler. Lustre vitreous. Translucent. Specific gravity 3.19. It occurs at Joachimsthal in Bohemia, and has not been quantitatively analysed.

Samaraskite, Uranotantalite, Ytrotlmenite, is a compound of oxide of uranium with niobio and tungstic acids. From Miask and the Ural.

URAN-BLOOM. [URANIUM.]

URAN-MICA. [URANIUM.]

URANOCENTRON. [IOUANIDE.]

URANO/SCOPUS, a genus of Acanthopterygious Osseous Fishes of the Perch Family, and very nearly related to the Weavers (*Trachinurus*) of the British seas. One or two species inhabit the Mediterranean. The head is nearly cubical, and the eyes placed in the flat summit, so that they look upwards; hence the name. The mouth is turned up in a similar manner. This arrangement agrees with the habits of the fish, which buries itself in sand all but the summit of the head, and thus lies in wait for its prey. Its colour resembles the sand in which it lives.

URANOTANTALITE. [URANIUM.]

URAO, a variety of Sesqui-Carbonate of Soda. [SODIUM.]

URARI. [STRYCHNOS.]

URCEOLA, a genus of Plants belonging to the natural order Apocynaceæ, so named by Dr. Roxburgh from urceolus, 'a pitcher,' in consequence of the form of its corolla. The genus *Urceola* is confined to the Malayan peninsula, and the islands of Sumatra and Penang; but as it is by some botanists considered not to differ from the *Vakeu* of Madagascar, the genus may have a wider distribution. It has the calyx small, 5-partite. Corolla nreolato; tube elongated,

ventricose, 5 cleft. Stamens 5, anthers sagittate. Follicles 2; seeds numerous, glabrous.

U. elastica, or Caoutchouc-Viue, is shrubby and twining, climbing over trees to a great extent, sometimes as much as 200 paces; with oval opposite leaves, and terminal panicles. From wounds made in the bark of this plant there oozes out a milky fluid, which on exposure to the open air separates into an elastic coagulum, and watery liquid apparently of no use. After the separation takes place, this coagulum is not only like American Caoutchouc, or Indian-Rubber, but possesses all the same properties as first ascertained by Dr. Roxburgh ('Asiat. Res.' v. 171.) He states that a ball of it externally has the appearance of American Caoutchouc; when cut into, it is of a light brown colour, till the action of the air darkens it. This ball, measuring 9½ inches in circumference, and weighing 7¼ ounces, in simply falling from a height of 15 feet, rebounded about 10 or 12 times, which is of itself an indication of the goodness of the Caoutchouc. Dr. Roxburgh also found that slips of it were capable of bearing a greater degree of extension and contraction than the American. When they broke, the elasticity was so great, that each end returned to its respective mass. The least pressure with the finger and thumb united different portions as perfectly as if they had never been separated: this property of Caoutchouc has been considered a much more modern discovery. [INDIAN-RUBBER.]

URCEOLARIA, a genus of Crustaceous Lichens, belonging to Fée's family *Lecanoreæ*. The characters of this genus are as follows:—Thallus crustaceous, spreading, adnate, uniform; the apothecia, reproductive organs, are orbicular, with the disc concave, coloured, and immersed in the crust; the border of the apothecium is formed of the crust, and has the same colour. Hooker, in his 'British Flora,' enumerates six British species of *Urceolaria*. They are generally found on rocks, stones, and walls. Two of the species *U. scruposa*, the Common Urceolaria, and *U. cinerea*, the Gray Urceolaria, are used for dyeing.

URCHIN. [ERINACEUS.]

URCHIN, SEA. [ECHINIDÆ.]

UREDINACEÆ, a family of *Fungi*, belonging to the sub-order *Sporiferi*. It includes the various forms of *Fungi* which occur on diseased vegetable tissues, and which are hence called Blights. The spores are single, often partitioned on more or less distinct sporophores, flocci of the fruit obsolete or mere peduncles. [FUNG.]

URE'DO. [FUNG.]

URE'NA, a genus of Plants belonging to the natural order *Malvaceæ*. Like other Malvaceous plants, the species of *Urena* abound in strong and serviceable flax-like fibres, which are well fitted for conversion into cordage. *U. lobata* and *U. sinuata* are specially mentioned as employed for this purpose in India.

URETER. [BLADDER.]

URETHRA. [BLADDER.]

URIA. [GUILLEMOTS.]

URINARY SYSTEM. [URINE.]

URINARY ORGANS. [KIDNEYS.]

URINE is a fluid secreted from the blood by the kidneys. This fluid in a healthy person when recently voided is acid, transparent, usually of a pale amber or straw-colour, of a brackish taste, peculiar odour, and of a specific gravity varying from 1.010 to 1.030. The character of the urine however is apt to be altered by a variety of circumstances: it differs, for instance, according to the time of the day at which it is passed, whether before or after a meal, and according to the quantity and quality of the food and drink consumed. Urine has therefore been divided into two kinds, that of assimilation, and that of the blood. The urine of the blood is that voided at a considerable time after food has been taken, when the process of digestion is complete, and the chyle has entered the blood: it has the properties of urine in an eminent degree, and from it we are enabled to learn the state of the kidneys and system in general. The urine of assimilation varies, being sometimes limpid and colourless, when a great quantity of fluids has been taken; at other times, after a full and solid meal, of a deep colour, and becoming turbid on cooling.

The character of the urine is affected by the seasons; in winter the kidneys are excited to greater activity than in summer, nor is the reason of this difficult of explanation. All the emunctories of the body act, as occasion may require, as mutual suppeditories. Now, in cold weather the perspiration is more or less suppressed; and were it not that the action of the kidneys was increased, we should be liable to plethoras, or repletions of the most dangerous nature. Hence it happens that when the perspiration is abundant, the urine is scanty and high coloured, and contains a strong impregnation of saline ingredients; when the perspiration is checked by any cause, the urine is copious, limpid, and its proper salts more diluted. The state of the mind has also a great influence on the urine: any sudden shock usually increases the quantity of this fluid, and it is then almost without odour or flavour, like water.

The colour of the urine of persons in health is usually of a pale amber colour, becoming slightly turbid towards the centre, seven or eight hours after having been passed, and shortly depositing a sediment, that rises up in the form of a cone from the centre of the fluid. This deposition, which at first is in small quantity, increases until putrefaction renders the whole of the urine turbid. The colour of

urine varies. It becomes almost colourless if much drink has been swallowed; red after long fasting, the use of water-cresses, beet, sorrel, and madder; it is tinged blackish by chalybeates; yellow by saffron, turmeric, and rhubarb: the astringent principle of galls and other substances containing tannin is detected in the urine by this fluid assuming a bluish or greenish tint on any of the salts of iron being added to it.

The odour of healthy urine is somewhat aromatic, without acidity, ammoniacal smell, or fetid taint, and resembles in a great degree the odour of the perspiration of a healthy man. The urine of persons affected with stone in the bladder often acquires a highly offensive odour, and the urine of diabetic patients has usually a sweet wheyey smell. Certain substances, when eaten, or even when respired, impart a peculiar odour to the urine. Garlic and other strong-smelling substances impart their peculiar odour to the urine, and the odorous principles of asparagus, cauliflowers, fennel, juniper berries, valerian, castor, balsam of Peru, copaiba, cubebs, and many other substances, likewise pass through the blood into the urine.

Healthy urine almost always gives an acid reaction; it becomes ammoniacal only by a prolonged exposure to the atmosphere, for it remains perfectly unchanged if kept in a vessel well stopped. Its ammoniacal transformation is owing to the spontaneous decomposition of the urea. It appears that this conversion may even take place in the kidneys under the influence of disease, especially in putrid and other adynamic fevers: then the urine is alkaline as it passes from the bladder, and proportionally so as it contains less urea.

In health the quantity of urine passed in 24 hours is subject to variation from temperature, the diet, and exercise of the individual, as well as other circumstances, and it is therefore impossible to fix a standard applicable to every case. Haller estimated the quantity voided in 24 hours to be as high as 49 ounces; Rye considered 40 ounces an average quantity in the same time; whilst Dr. Prout says that, if we consider that the quantity varies in this country from 30 ounces in the summer to 40 ounces in the winter, we should probably be very near the truth as regards a person in good health, and who does not drink more than nature requires. Lehmann gives 54 ounces as an average occurring in the case of nine healthy young men on whom he experimented.

The specific gravity of healthy urine varies in different individuals from 1.010 to 1.030. The late Dr. James Crawford Gregory found the mean specific gravity of urine in 50 apparently healthy subjects in Edinburgh, during the months of September, October, and November, at 2 o'clock in the day, to be 1.02246. Dr. Prout considers the average specific gravity to range from 1.015 in the winter to 1.025 in the summer. The specific gravity is liable however to change according to circumstances. According to Vogel it is greatest after the principal meal, dinner. It is least when liquids are being drunk.

The following table was constructed by Dr. Henry for ascertaining, without the trouble of evaporation, the quantity of solid extract contained in the pint (16 ounces) of urine of different specific gravities from 1.020 to 1.050:—

Specific Gravity at 60° F.	Solid Extract in a wine pint, in grains.	Solid Extract in a wine pint, in ounces.
		oz. drs. sc. grs.
1.020	352.4	0 6 1 2
1.021	401.6	0 6 2 1
1.022	420.8	0 7 0 0
1.023	440.0	0 7 1 0
1.024	459.2	0 7 1 19
1.025	478.4	0 7 2 18
1.026	497.6	1 0 0 17
1.027	516.8	1 0 1 16
1.028	536.0	1 0 2 16
1.029	555.2	1 1 0 15
1.030	574.4	1 1 1 14
1.031	593.6	1 1 2 13
1.032	612.8	1 2 0 12
1.033	632.0	1 2 1 12
1.034	651.2	1 2 2 11
1.035	670.4	1 3 0 10
1.036	689.6	1 3 1 9
1.037	708.8	1 3 2 8
1.038	728.0	1 4 0 8
1.039	747.2	1 4 1 7
1.040	766.4	1 4 2 6
1.041	785.6	1 5 0 5
1.042	804.8	1 5 1 4
1.043	824.0	1 5 2 3
1.044	843.2	1 6 0 3
1.045	862.4	1 6 1 2
1.046	881.6	1 6 2 1
1.047	900.8	1 7 0 0
1.048	920.0	1 7 1 0
1.049	939.2	1 7 2 19
1.050	958.4	1 7 2 18

In order to ascertain the quantity of solid matter in 16 fluid ounces of urine of a given specific gravity, it is only necessary to refer to

the above table. The following table gives the composition of the urine as given by various chemists:—

	Berzelius.	Simon.	Müller.	Marchand.
Animal and de- strucible principles.	1. Water	933.00	936.000	933.199
	2. Urea	30.10	14.578	32.675
	3. Lactic Acid	1.00	0.710	1.065
	4. Free lactic acid, lactate of ammonia, and amal- matters not sepa- rable from them	17.14	12.940	14.1326
	5. Mucus of the bladder	0.32		0.283
	6. Sulphate of potash	3.71	3.508	3.587
	7. Sulphate of soda	3.16		3.213
	8. Phosphate of soda	2.94	2.330	3.056
	9. Phosphate of ammonia	1.65		1.552
Alkaline and earthy salts.	8. Chloride of sodium	4.45	7.280	4.218
	Muriate of Ammonia	1.50		1.653
	9. Earthy phosphates, with a trace of fluoride of lime	1.00	0.654	1.210
	Silica	0.03	a trace.	
	Total	1000.00	998.000	990.7710

In addition to these matters, which constantly exist in healthy urine, this fluid occasionally contains the following substances:—

- Albumen; fibrin; red particles.
- Various acids, colouring-matters, &c., formed from or accompanying the lithic acid; nitric acid.
- Xanthic oxide.
- Cystic oxide.
- Sugar; oxalic acid; oxalate of lime; carbonic acid.
- Hippuric acid; benzoic acid.
- Kiestine.
- Biliary matter.
- Fat and chylous matter.
- Spermatozoa.
- Foreign matters.

We shall proceed to notice most of those substances separately which are found in healthy urine.

Water is the basis of all animal fluids, and forms a very large proportion of urine. Sometimes an increase of the watery portion takes place, whilst the other principles remain the same, or become diminished. In this state of the urine, the urea and the salts bear to each other nearly their ordinary proportion, but are considerably deficient in their absolute quantity. Sometimes the increased flow of urine involves an increased proportion of a natural ingredient, as of urea, or of unnatural ingredients, as of albumen or sugar. On the other hand, the proportion of water is not unfrequently diminished below the natural standard, as in various forms of urinary suppression; and sometimes, when the cause of this suppression is mechanical, the urine is simply diminished in quantity, while its composition remains the same. At other times the suppression is connected with deranged action of the kidneys, and while the proportion of water is diminished, the other ingredients are relatively much increased, as in various forms of gravel and calculus. Drinking water and liquids containing water increases the quantity in the urine. Becker says that drinking pure water increases the quantity of solid matters carried off by the kidneys, but that tea, coffee, beers, and wines, though containing an equal quantity of water, diminish the quantity of solid matters excreted by the urine.

Urea is the principal solid element of the urine of *Mammalia*. It may be obtained in several ways. Liebig recommends the urine to be evaporated at 200° to a thin syrup, then adding an equal volume of colourless nitric acid (specific gravity 1.35): nitrate of urea is thus obtained, while the colouring matter is destroyed with brisk effervescence. The nitrate of urea which is formed is dissolved in water, re-crystallised, and neutralised by potash or baryta. The whole is then to be gently evaporated to dryness after separating as much nitrate of potash or baryta as possible, and the dry mass digested in alcohol, which dissolves only the urea, and by spontaneous evaporation yields it in large transparent prismatic crystals. Urea has been artificially obtained from cyanate of ammonia by Wohler. It forms 4-sided prisms, resembling nitre in appearance. It is soluble in both alcohol and water. When heated it melts, gives off ammonia, and finally solidifies, being in a great measure converted into cyanic acid and ammonia. It readily unites with nitric, oxalic, and acetic acids. By the addition of nitric acid to urine, crystals of nitrate of urea may be detected under the microscope. Urea is composed of the four organic elements, carbon, hydrogen, oxygen, and nitrogen, according to the formula, C_2, N_2, H_4, O_2 . These elements arranged thus, C, N, O, H, O, N, H_2 , form cyanate of ammonia. When urine is left in contact with the mucus usually suspended in it, the mucus begins to decompose, and excites in the urea such a reaction with the elements of

water, as to convert the urea into carbonate of ammonia. This is the reason why urine speedily becomes alkaline, though acid when voided. If the urine is filtered from the mucus as soon as passed, it remains for a long time unchanged.

The ultimate source of urea in the urine is undoubtedly the metamorphosis of the muscular and nervous tissues of the body. It has been found, that in proportion to the muscular exercise taken, is the urea increased in the urine. Urea is also found in greater quantities in the urine of children, in whom the vital processes are more active than in the urine of adults. A question has arisen, as to whether urea is formed by the secreting energies of the kidney, or is merely separated from the blood by this organ. The fact of urea having been detected in the blood by Strahl, Lehmann, and others, would lead us to the conclusion that the latter is the fact. Another question then occurs, as to whether the urea in the blood is the result of the immediate metamorphosis of the tissues, or is formed by the intervention of other compounds. It appears that urine is easily formed from creatin, a substance that is the result of the decomposition of flesh, and it is not improbable that creatin is the source of urea in the blood. Although it has been generally supposed from the effect of arresting the function of the kidney that urea in the blood is a deadly poison, recent experiments have shown that a considerable quantity of urea may be injected into the blood without the destruction of life. It is probable that urea destroys life by becoming converted in the blood into carbonate of ammonia.

The quantity of urea secreted depends, as stated above, on age and muscular exertion, but these are not the only conditions which affect the quantity of urea in the urine. The quality of the food has an especial influence on this substance. Bischoff found, in a course of experiments on dogs, that one dog when taking 4000 grammes of beef discharged 190 grammes of urea daily, and when living on 500 grammes of potatoes and 250 grammes of fat excreted not more than from 6 to 8 grammes. Siegmund also, in a series of experiments performed on rabbits, found that the quantity of urea gradually diminishes with the quantity of the food.

Uric Acid invariably exists in healthy urine, and can be easily precipitated by the addition of any acid. As the production of this acid in the system is intimately connected with the nature of the food and the powers of digestion, deposits of this acid, as might be expected, are of frequent occurrence. This acid is either deposited in the form of powder (or, as it is usually called, amorphous sediment), or in the form of crystals and large concretions. The amorphous sediment varies extremely in its colour, from snow-white to fawn colour or reddish-brown, occasionally assuming a series of beautiful tints, varying from the most delicate pink to the brightest carmine, or very nearly to the deepest crimson. These varieties of colour depend on the greater or less proportion of the colouring-matter of urine, and a peculiar principle (phosphate of ammonia) developed in the kidneys. In this form the uric acid is usually in combination with ammonia. Healthy urine contains urate of ammonia to the amount of about 1-800th part, and the salt requires about 480 times its weight of cold water to dissolve it. We see therefore that if by any derangement in the digestive organs the quantity of urate of ammonia should be increased in the urine, a portion of it would of necessity be thrown down, as the urine would not be sufficient to hold the whole of it in solution. Urine containing this amorphous deposit varies in colour according to its sediment. It is always acid, and usually of high specific gravity, and is rendered transparent by the application of heat, unless the urine be albuminous or contain mucus.

When a deposit of urate of ammonia is examined under the microscope, it is found to be made up of a series of amorphous granules, presenting no approach to a crystalline arrangement, unless, as very frequently occurs, free uric acid be present. On gently warming the drop of urine submitted to examination the deposit vanishes, and then any crystals of uric acid.

Uric Acid is often deposited in a crystalline form, and is found most generally of a yellow, orange-red, or brick-dust colour, never however

Uric Acid Crystals.

presenting the beautiful carmine tints occasionally possessed by urate of ammonia. It is sometimes met with isolated and unmixed with any amorphous deposits, but more generally is found in company with the urate of ammonia. On being allowed to subside two distinct layers are formed, the lowest consisting of uric acid, often in crystals

sufficiently large to be distinguished by the unassisted eye; and above this a dense stratum of amorphous urate. Under the microscope uric acid presents a number of forms, but the rhomboid of a tolerably distinct lozenge-shape is the most frequent form. Several secondary forms, probably depending on a variable portion of colouring-matter being present, frequently occur; among these are the table, the flattened cylinder, sharply serrated lozenges, and stella formed by the cohering of elongated rhombs.

Uric Acid appears to be formed in the system under the same circumstances as urea; but its formation in the blood seems to be anterior to the urea. Uric acid appears to be converted into urea by the process of oxidation, hence its development is increased by sedentary pursuits, and arrested by active exercise. The acidity of urine does not depend so much on uric acid as on acid phosphate of soda, which is formed by some acid uniting with the soda of the phosphate and converting it into a superphosphate. The formula of Uric Acid is C_{10}, N_4, H_4, O_6 .

Although lactic acid is said to be present in human urine, it does not appear that it occurs in healthy human urine; it is very soon developed in the urine when the oxidation in the blood is to any extent impeded. Hence it is found when fever is present, and in those disturbances of the respiratory and digestive organs which lead to a deficient oxidation of the blood.

The extractive matters of the urine referred to in the analyses consist of substances of which our knowledge is daily increasing. Thus, creatin and creatinin are found in normal urine, although their quantity and relations have not been well made out. We may also refer to this bead hippuric acid. It is well known that when animals take food containing benzoic acid, that their urine contains hippuric acid. Particular kinds of diet favour the development of hippuric acid at the expense of uric acid, whilst a mixed diet is unfavourable to the development of hippuric acid. Formic acid may be also mentioned here as a substance recently detected in healthy urine, and probably included in extractive matters.

The colouring matters of the urine are not specially named in chemical analyses. That some one substance, accordingly as it abounds or is absent, produces the various shades of yellow, red, and brown observed in urine, is not improbable. Vogel, who has devoted much attention to this subject, is of opinion that the urine-pigment is formed from the hæmation of the blood, and is produced by a decomposition of the blood-corpuscles. On this ground he regards the amount of pigment in the urine as an index to the amount of disintegration of the blood-cells in a given time.

Mucus always exists in healthy urine in minute quantities, and the following are the appearances which it assumes:—After the urine has stood for some time in a tall glass vessel, the lower strata of the fluid will be found to have lost their transparency, and an exceedingly light nebulous-looking substance will be found floating in the vessel. If collected in a filter, mucus, when moist, is always more or less transparent; and when dried, it has a shining appearance. Mucus is not coagulated by boiling, which distinguishes it from albumen; it is in great part soluble in the acetic and nitric acids, but not in the sulphuric acid; it is also soluble in caustic potash. Under the microscope it presents cells larger than those of the blood, and delicately granulated on their surface. With these will be found, in the transparent liquid, a number of minute granular points.

Sulphuric Acid and Sulphates.—These are formed by the oxidation of the sulphur of the protein-compounds; and it has been shown by Dr. Beuce Jones, that they are abundant in proportion to the destruction of the tissues and the oxidation of the sulphur.

Phosphoric Acid and Phosphates.—These appear to be derived as the sulphates from the disintegration of the tissues containing phosphorus, which is more especially the case with the nervous. The

Triple Phosphate Crystals.

phosphates of the alkalis are found to be increased in diseases in which the activity of the nervous system is increased. The phosphates

of lime and magnesia are naturally found in the urine, arising from the disintegration of the osseous tissue. Their deposit so as to form calculi depends on the absence of the acid phosphate of soda in which they are soluble, and not to their redundancy in the system. During the deposit of the ammoniaco-magnesian phosphate, the urine is sometimes neutral, often acid, and never alkaline, unless the deposited phosphate is really a secondary result. On exposing to heat urine of this kind, the triple salt is deposited, the precipitation often being attended with an evident evolution of carbonic acid. Dr. Bird has figured two distinct forms of triple phosphate, each containing a different proportion of ammonia, and readily distinguishable by the shape of their crystals. The first appears under the microscope of a weak magnifying power as a series of beautifully-defined transparent crystals, being either prisms or some modifications of them. The second forms elegant stellar crystals, or thin crystalline laminae, resembling foliage.

Where this salt exists in combination with phosphate of lime, forming the well-known fusible compound, the characters of the urine scarcely differ from those met with in simply phosphatic secretion.

Chloride of Sodium.—This substance seems to result from the kind of food rather than the disintegration of the tissues, and thus it is found varying in quantity according to the nature of the food.

Soda, Potash, Ammonia.—The two fixed alkalies exist in the urine in combination with the sulphuric, phosphoric, muriatic, and lactic acids; whilst ammonia is found in combination only with the hydrochloric, phosphoric, and uric acids.

Lime.—If to urine, deprived by filtration of its vesical mucus, an excess of caustic ammonia be added, a very bulky precipitate is thrown down. This precipitate (besides a minute quantity of ammonio-phosphate of magnesia) contains the lime in union with phosphoric acid.

Magnesia, like lime, in combination with phosphoric acid, is one of the constituents of bone earth; but it forms a very small part. It is also a principal ingredient of certain urinary calculi, into two species of which it enters.

Silica, or Silic Acid, is reckoned by Berzelius amongst the constituents of healthy urine, and it has been occasionally detected in urinary calculi.

For an account of the products only occasionally found in the urine, see the article URINE, PATHOLOGY OF, in ARTS AND SC. DIV.

On examining the sediment of urine under the microscope, a number of substances presenting definite forms will be seen. The mucus-corpuscles have been referred to above, but there are other morphological elements which probably supply the chemist with the quantity of matter placed under the head of extractive matters and inucus. These are as follows:—

1. The pavement-epithelium of the urinary passages and bladder, cells of which are never wholly absent.
2. Tube-like or cylindrical bodies. These are casts of the tubes in the kidneys, and are frequently found in large quantities in diseased conditions of the organs.
3. Spermatozoa, which are often found in normal urine, arising from natural causes.
4. Filamentous *Fungi* are developed in urine after it has been kept some time, and arises under the same circumstances as the various forms of ferment *Fungus*.
5. *Infusoria*, especially those called *Vibrio*, are found present in decomposing urine.

The foreign substances which are accidentally found in the urine are referred to in the article MICROSCOPE, USES OF THE.

(Bowman, *Medical Chemistry*; Beale, *The Microscope in its Applications to Chemical Medicine*; Gregory, *Handbook of Inorganic Chemistry*; Bence Jones, *On Animal Chemistry in its Application to Stomach and Renal Diseases*; G. E. Day, *Contributions to Urology*; *British and Foreign Medico-Chirurgical Review*, July, 1855.)

UROMASTIX. [DRACONINA.]

URSIDÆ. Under the article BEAR will be found a full account of the species of the genus *Ursus*. This is a genus placed in the last edition of the 'Systema Naturæ' that underwent the revision of Linnæus, between *Mustela* and *Didelphis*, and includes the following species—*arctos*, *meles*, *lotor*, and *luscus*: in other words, it consists of the True Bears, the Badger, the Raccoon, and the Wolverine or Glutton.

We shall here give an account of the other genera of *Ursida*, and illustrations of the organisation of the genus *Ursus* (Linn.):—

The cylindrical bones of bears come nearer to those of man than the same bones in any other quadruped: the femur especially, although there is but a slight depression for the ligamentum teres, is closely approximated to the same bone in the human skeleton; and hence the faculty possessed by the bear of rearing itself on its hind-legs and dancing. The caudal vertebra in every well-preserved skeleton—those in the Museum of the College of Surgeons for instance—extend beyond the pelvis.

Dental Formula:—Incisors, $\frac{6}{6}$; Canines, $\frac{1-1}{1-1}$; Molars, $\frac{6-6}{7-7} = 42$.

Teeth of Bear.

Skeleton of Polar Bear (*Ursus arctos*, *Thalarctos maritimus*).

Procyon (Storr.), the Raccoons, have the three last molars with blunt tubercles on their crowns. Muzzle pointed. Ears small. Tail very long and hairy. No anal follicles. Six ventral mammae. Feet pentadactyle: claws sharp; the entire sole of the foot applied to the ground, when the animal is stationary only; in progression the heel is raised.

Raccoon (*Procyon lotor*; *Ursus lotor*, Linn.). (E. T. Bennett.)

Dental Formula :—Incisors, $\frac{6}{6}$; Canines, $\frac{1-1}{1-1}$; Molars, $\frac{6-6}{6-6} = 40$.

Teeth of Raccoon.

P. lotor (*Ursus lotor*, Linn.), is the Raton of the French; Raccoon ('Coon in clipped language) of the Anglo-Americans; Mapach, Yllamaton, Maxile, and Cioatlamacazque of the Mexicans; and Raccoon Bear of Pennant.

The head is round, with a narrow tapering nose projecting beyond the month, black at the end, and flexible: the lips black. Eyes moderately large and round, with a circular pupil. Elliptical ears low, but erect, with rounded tips, dirty white. Whiskers strong. Short-haired muzzle, dirty white, the colour extending round the cheek and over the eyes. A dark brown mark across the eyes and cheek, and another between the eyes, extending from the forehead. Back grizzled. Belly paler than the back. Tail bushy, not unlike a fox's brush, dirty white, annulated with dark rings. Length of head and body, 2 feet; of tail (vertebræ) $9\frac{1}{2}$ inches.

It is a native of the North of America. Several specimens are to be seen in the Gardens of the Zoological Society, Regent's Park.

Mellivora (Storr.).—General characters corresponding with those of *Gulo*. [GULO.] Feet pentadactyle.

Dental Formula :—Incisors, $\frac{6}{6}$; Canines, $\frac{1-1}{1-1}$; Molars, $\frac{4-4}{4-4} = 32$.

Ratel (*Mellivora Capensis*).

Teeth of Ratel. (F. Cuvier.)

In some points this genus approximates to the Hyænas: in others, to the Polecats, Zorillas, and Martins.

M. Capensis.—This appears to be the *Viverra Capensis* of Schreber, *Gulo Capensis* of Desmarest, *Mellivora Capensis* of F. Cuvier, *Viverra mellivora* and *Ursus mellivorus* of Blumenbach, *Taxus mellivorus* of Tiedemann, *Meles mellivora* of Thuuherg, Stinkbinksen of Kolbe (?), Ratel of Sparrmann, Fizzler Weesel and Ratel of Pennant, Honey Weesel of Shaw, Honig Preter of the Dutch Cape Colonists, and Blaireau Puant of La Caille.

The head is rather smooth, but stiff and wiry. Body above from the top of the head to the root of the tail dull ash-gray, whitest towards the head. Muzzle, space round the eyes and ears, limbs, all the under parts, and rest of the tail, black. Claws on the fore-feet long, the middle three longest, the internal claw placed much more backward than the rest. Bulk about that of a Badger. Total length three feet, the tail about a sixth of the length. Height about 10 or 12 inches.

The hide of this quadruped is so tough and loose, that, according to Sparrmann, if anybody catches hold of it by the back part of the neck, it is able to turn round, so to speak, in its skin, and bite the offending arm. The claws of the fore feet are longest, and well formed for grubbing. The bees, according to the description of the author last quoted, who drew his information from the Hottentots, furnish the principal means of subsistence to the Ratel. These insects, in that part of South Africa where the Ratel is found, usually inhabit the deserted lairs and burrows of the Ethiopian Boar, the Porcupine, &c., and, according to the accounts given, the Ratel, which preys in the evening, ascends to the highest parts of the deserts to look out, and will then raise its paw before its eyes to prevent their being dazzled by the sun. Here he watches and listens for the Honey-Guide Cuckoo [INDICATORINÆ], which serves both the Hottentot and quadruped as a conductor to the bees' store, or for the flight of the bees themselves. If the beast have luck to trace the guide or the insect it follows, and if the nest be on the ground or near it, he undermines it with his natural digging instruments, and secures the contents. If the nest be in the tree, the Ratel, which cannot climb, gnaws the trunk in its unavailing rage, leaving marks which the Hottentot well knows as indicative of the treasure above.

Mr. Bennett well observes that the dentition of the Ratel is much at variance with the diet above attributed to him, and that the accuracy of these accounts may be doubted. "It requires," says he, "the most positive evidence to convince us that an animal, the number and disposition of whose teeth correspond more closely with those of the cats than any other quadruped with which we are acquainted, and exhibit a carnivorous character scarcely, if at all, inferior to that which is evidenced by the same organs in the hyænas, should subsist entirely, as from these accounts we are left to believe, upon the petty rapine of a hive of bees and the honied produce of their comb. Still, there exist such decisive marks of a diminished capacity for preying on animal food, in the thickset and clumsy form of its body, the short-

ness of its limbs, its partially plantigrade walk, the structure of its muzzle, and even in the form of the teeth themselves, as to induce us to pause before we determine to reject the popular testimony as unworthy of credit, although we must regard it as doubtful on some particular points, and insufficient and imperfect on the whole."

It inhabits the Cape of Good Hope.

Meles (Brisson), the Badger, has the following—

Dental Formula:—Incisors, $\frac{6}{6}$; Canines, $\frac{1-1}{1-1}$; Molars, $\frac{4-4}{6-6}$ = 36.

Teeth of Badger.

[BEAR; BADGER; PANDA; ICTIDES; GULO; VIVERRIDÆ.]

URSUS. [BEAR; URSIDÆ.]

URTICA (from 'uro'), a genus of Plants known under the common name of Nettle. Nettle is the same word as the Anglo-Saxon 'netel,' or 'nedl,' a needle, which is applied to these plants on account of their possessing small bristles or prickles which have a stinging property. This genus is the type of the natural order *Urticaceæ*. The flowers are either monœcious or diœcious. The stamiferous flowers have a single perianth of 4 leaves, containing the rudiment of a pistil. The pistilliferous flowers have a single perianth of 2 leaves; a sessile stigma, and a dry fruit containing a single seed. Most of the species are herbaceous plants or under-shrubs, and are found in Europe, Asia, and America. Three of the species, of which there are about 40, are British.

U. pilulifera, the Roman Nettle, has opposite ovate serrated leaves, with transverse nerves, and the pistilliferous flowers pedunculated, and arranged in globose spikes. This plant is found in England, under walls and amongst rubbish, principally near the sea, in the counties of Norfolk and Suffolk. It has also been found in the south of Ireland. This is the most virulent of our native nettles.

U. dioica, the Great Nettle, has ovate-acuminate leaves, cordate at the base; the flowers are diœcious in clusters, much branched, and the clusters in pairs. This is a very common plant throughout Europe, in waste places, under walls and hedge-banks. The tops of this plant, when young in spring, are sometimes eaten as a potherb, especially among the humbler classes in Scotland.

U. urens, Small or Garden-Nettle, has opposite elliptical leaves with about 5 nearly parallel ribs, with nearly simple clusters of flowers.

U. tenacissima, like some of the other nettles, as well as the hemp and the hemp, belonging to the same natural family, abounds in ligneous fibre, which may be converted into very strong cordage. This is the Caloeo of Marsden, Rami of the Malays, a native of Sumatra, also of Rungpore, where it is called Kunkams, and which Dr. Roxburgh found one of the strongest of all the vegetable fibres which he subjected to experiment.

The woody fibres of other species of *Urtica* are employed in making linen. The *U. (Boehmeria) nivea* yields a remarkably fine fibre, with which delicate fabrics are made in India.

URTICACEÆ, Nettles, or Nettleworts, a natural order of Plants. The plants belonging to this order are trees, shrubs, and herbs, yielding in some instances a milky juice. The leaves are alternate,

and usually covered with asperities or with hairs furnished with a stinging secretion; the stipules are membranaceous, and are deciduous or convolute in veneration. The flowers are monœcious or diœcious, either scattered or collected together in catkins or in close heads. The calyx is membranous, lobed, or persistent. The stamens are definite in number, not united, and inserted into the calyx opposite its lobes; the anthers during aestivation are curved inwards, but are turned backwards with elasticity after bursting. The ovary is superior, containing a solitary erect or suspended ovule with a simple stigma. The fruit is either a simple indehiscent nut, surrounded by a membranous or fleshy calyx, as in *Boehmeria* (fig. 1); or it is a fleshy receptacle, either

Fig. 1.

Boehmeria cordata.

a, branch, with flowers; b, single flower; c, collection of fruits; d, section of fruit, lying in which is seen the seed and embryo.

covered by numerous nuts lying among the persistent fleshy calyxes, as in *Dorstenia*, or the nuts are inclosed in the cavity of the receptacle, as in the Common Fig (fig. 2); or it may consist of a single nut covered

Fig. 2.

Common Fig (*Ficus Carica*.)

a, branch, with leaves and figs; b, section of a fig, showing the flowers inclosed within the fleshy receptacle; c, male flowers separated; d, section of ovary; e, section of seed, showing curved embryo.

hy a succulent involucre. The embryo is straight, curved, or spiral, sometimes without alumen; the cotyledons are flat, and the radicle points to the hilum.

The order, as thus defined, includes several groups of plants which are frequently separated, as the *Artocarpeæ* of Robert Brown, the *Batidæ* of Martius, and the *Morææ* of Endlicher.

This order brings together plants growing all over the world, possessing very different properties, and yielding very various and useful products. The Stinging Nettles [*URTICA*] form the type of the order. To it belongs also the deadly *Upas*. [*ANTIARIS*.] The wholesome Fig, the celebrated Banyan, and species yielding deadly poisons belong to the genus *Ficus*. [*FIGUS*.] The Bitter Hop [*HUMULUS*], the Acid Mulberry [*MORUS*], and the Narcotic Hemp [*CANNABIS*], and famous Cow-Tree [*COW-TREE*], all belong here. The sap of many of the species, especially those belonging to the division *Artocarpeæ* is milky. [*ARTOCARPEÆ*; *MORACEÆ*; *ARTOCARPUS*; *BEHMERIA*; *DORSTENIA*.]

URUS. [*BISON*; *BOVIDÆ*.]

USNEA, a genus of Plants belonging to the natural order of Lichens. The *Usnea plicata*, in common with the *Roccella tinctoria* and other Lichens, is used as a dye.

UTRICULARIA, a genus of Plants belonging to the natural order *Lentibulariæ*. It has the calyx with two equal leaves, a personate

spurred corolla, a 2-lipped stigma, a globose capsule of one cell, and several seeds fixed to a central receptacle. There are only three species, *U. intermedia*, *U. vulgaris*, and *U. minor*. They are all inhabitants of Great Britain. The metamorphosed leaves attached to the roots of all the species are furnished with little bladders, which, when the plant is growing at the bottom of a ditch or pond, are filled with water.

UTRICULUS, in Botany, a form of Fruit. [*FRUIT*.]

UTROPHUS. [*IGUANIDÆ*.]

U'VULA. [*PALATE*.]

UWAROWITE, *Chromium Garnet*, a Mineral occurring crystallised in Rhombic Dodecahedrons. Colour emerald green. Hardness 7·5. Lustre vitreous. Nearly transparent. Specific gravity 3·41. It is found at Bessersk, in the Ural Mountains. Its analysis by Komonen gives—

Silica	37·11
Alumina	5·88
Oxide of Chromium	22·54
Protoxide of Iron	2·44
Lime	30·34
Magnesia	1·10
Water	1·01
	—100·42

V

VACCINACEÆ, *Cranberries*, a natural order of Exogenous Plants.

The species of this order are shrubby plants, with round irregularly angled stems and branches; simple entire alternate coriaceous leaves, with a solitary or racemose inflorescence. The calyx is superior and entire, or with 4, 5, or 6 lobes, sometimes deciduous. The corolla is monopetalous, and its lobes correspond to those of the calyx, and are alternate with them. The stamens are free, and are generally double the number of the lobes of the calyx, and are inserted into an epigynous disc; the anthers are terminal, 2-celled, bursting by pores, and furnished with two horns. The ovary is inferior, surmounted by the epigynous disc, 4-5-celled, with one or many seeds in each cell; the style and stigma are both simple. The seeds are very small, with a straight embryo in the midst of a fleshy albumen; the cotyledons are very short, and the radicle is long. This order is made by many botanists a section of *Ericaceæ*. It differs from *Ericaceæ* in possessing an inferior ovary and a succulent fruit. It was placed by Richard in *Escalloniaceæ*, but it differs from this order in being monopetalous, and its anthers bursting by pores.

Vaccinaceæ. This genus consists of shrubby plants with alternate membranous leaves, often beset with resinous dots, and are either permanent or deciduous. The flowers are seated on pedicels, and are either solitary or arranged in simple racemes, generally drooping, without any odour, and tinted with various shades of red or pink. The calyx is 4-5-toothed; the corolla urceolate or campanulate, more or less deeply 4-5-cleft, with the limb reflexed; the stamens are 8 or 10, not attached to the corolla, with 2-horned anthers dehiscing at the summits, and sometimes furnished at the back with two spreading spurs or bristles; the style is longer than the stamens, and the stigma obtuse; the fruit is a berry, globose, depressed at the top, 4- or 5-celled, many-seeded, of a black purple, bluish, or red colour, generally eatable, though not always pleasant or wholesome in an uncooked state. The genus consists of about 50 species, which are known by the common names of Bilberries, Whortleberries, Bleaherries, &c.

V. Myrtillus, the Common Bilberry or Bleaherry, has solitary pedicels, 1-flowered, the leaves are serrated, ovate, smooth, the stem is acutely angular, and the calyx hardly divided. It is a small shrub about a foot high, and is a native of heaths, stony moors, and mountain-woods throughout Europe. It is abundant in Great Britain. In the north of England and Scotland the berries are gathered and used for making tarts; in Devonshire and in Poland they are eaten with clotted cream.

V. uliginosum, Great Bilberry, or Bog Whortleberry, has 1-flowered peduncles, with obovate, entire, veined, and deciduous leaves, with rounded stems. Like the last it is a small shrub, and attains a height of two feet. It is a native of Great Britain, and is found in mountainous hogs in Cumberland and Westmorland, but is more frequent in the Highlands of Scotland, being found nearly on the summits of the highest mountains. Its berries are very similar to those of the common whortleberry, but their flavour is not so agreeable.

V. Vitis-idaea, Red Whortleberry, or Cowberry, has terminal racemes of drooping campanulate flowers, with evergreen obovate leaves, dotted beneath, and their margins slightly revolute, and nearly entire. It is a low straggling shrub, with leaves resembling those of the Box, and pale flesh-coloured flowers. It is a native of dry places on heaths, mountains, and in woods, throughout Europe. It is plentiful in the north of England, Westmorland, Derbyshire, and Wales. This plant is the badge of the clan Macleod. The berries have a red colour, and possess acid and astringent properties. They are hardly eatable raw.

V. stamineum, the Green-Wooded American Whortleberry; *V. corymbosum*, the Naked Flowering Whortleberry; and *V. frondosum*, the Blunt-Leaved Whortleberry, or Blue Tangles, are American species.

V. Arctostaphylos, Oriental Bearberry, or Bear's-Grape Whortleberry, is a native of the coast of the Black Sea, where it was originally gathered by Tournefort, who was of opinion that it was the *Ἀρκτοστάφυλος*, or Bear's-Grape of Galen.

VACHELLIA, a genus of Plants belonging to the natural order *Leguminosæ*.

V. Farnesiana, a native of the East and West Indies, exudes from its bark a considerable quantity of gum. The flowers when distilled yield a delicious perfume.

VAGINULUS. [*LIMAX*.]

VALERIAN. [*VALERIANA*.]

VALERIAN, GREEK. [*POLEMONIUM*.]

VALERIANA, a genus of Plants, the type of the natural order *Valerianaceæ*. The species of this genus are herbs or undershrubs, with very variable leaves, and mostly reddish-white corymbose flowers. The limb of the calyx is involute during flowering, but it at last

Common Bilberry (*Vaccinium Myrtillus*).

1, branch, with fruit; 2, stamen, showing horned and porous anthers; 3, stamens seated on disc; 4, section of fruit; 5, seed with embryo.

The plants of this order are not common in Europe, but they are abundant in North America, extending to very high northern latitudes, and are not uncommon on high land in the Sandwich Islands. [*ERICACEÆ*; *VACCINIUM*.]

VACCINIUM, a genus of Plants, the type of the natural order

unfolds itself in the form of a feathery pappus, which is seated on the inferior ovary; the corolla is infundibuliform, gibbous at the base, and 5-lobed; the stamens are 3, and the fruit is indehiscent, 1-celled, and 1-seeded. This genus presents many diversities of form, although its species are obviously closely related.

V. officinalis, the Official or Great Wild Valerian, is a smooth erect plant, with furrowed stems, with all the leaves pinnated, the leaflets being serrated and lanceolate, in 7 or 8 pairs, with an odd one; the inflorescence is at first a corymb, but by growth becomes a panicle; the fruit is glabrous. This plant is a native of Europe, and by the sides of rivers and in ditches and moist woods is abundant in Great Britain. This plant was introduced into medicine, and admitted into the Pharmacopœia, on account of its being supposed to be the Phu (Φου of Dioscorides). The *V. Phu* of Linnaeus was afterwards supposed to be the genuine Phu, but Dr. Sibthorp discovered another species of Valerian in Greece, which Smith has named *V. Dioscoridis*, and which is probably the plant of Dioscorides. The root has a very strong smell, which is dependent on a volatile oil. It is very attractive to cats, and also to rats, and is employed by rat-catchers to decoy rats. It is much employed also in medicine at the present day. [VALERIAN, in ARTS AND SC. DIV.]

V. rubra, the Red Valerian, is often referred to the genus *Centranthus*. [CENTRANTHUS.]

V. dioica, the Small Marsh Valerian, is a glabrous erect plant, with a striated stem; the radical leaves ovate, undivided; those of the stem pinnatifid, with linear oblong leaflets; the stamens and pistils are on separate flowers in different plants, the corymbs of stamiferous flowers are loose, those of pistilliferous flowers are contracted; the lobes of the stigma are almost united; the fruit is smooth. This plant is a deciduous herbaceous perennial, very common in moist meadows, by the sides of rivers, and in ditches, throughout Europe. It is abundant in some parts of Great Britain.

Valeriana dioica.

1, cutting, with pistilliferous flowers; 2, ditto, with stamiferous flowers; 3, section of pistilliferous flower with fertile cell; 4, section of stamiferous flower; 5, section of sterile cell; 6, fruit with permanent feathery calyx.

V. Dioscoridis, the ancient Grecian Valerian, was first described by Smith, in the 'Flora Græca,' Dr. Sibthorp having discovered it near the river Limyrus in Lycia. Professor Edward Forbes, in his travels in Lycia, met with this plant in great abundance over a large district.

V. Phu, the Garden Valerian, is an erect glabrous plant with square smooth stems; the root-leaves entire, oblong or elliptic; those of the stem pinnatifid, with oblong lobes; the corymbs panicled; lobes of the stigma 3; fruit smooth, except in two hairy lines. This plant is a native of Europe, in Belgium, France, Switzerland, Silesia, &c. [CENTRANTHUS.]

VALERIANACEÆ, *Valerian* Words, a natural order of Exogenous Plants, belonging to Lindley's Aggregose group of Monopetalous Exogena. The order is composed of annual or perennial herbs or undershrubs with opposite exstipulate leaves. All the perennial species have roots more or less strongly scented; the annual are mostly inodorous. The flowers are either corymbose, panicled, or in heads, sometimes changing from one form into the other; the calyx is superior, the limb either membranous or forming a feathery pappus; the corolla is tubular, 3-6-lobed, regular or irregular, and sometimes spurred at the base; the stamens vary in number from 1 to 5, and are inserted into the tube of the corolla alternately with its lobes; the

ovary is inferior and 1-celled, with sometimes 2 imperfect and aborted cells; the ovule is solitary and pendulous, the style simple, and from 1 to 3 stigmas; the embryo is straight and without albumen, with a superior radicle. These plants are most nearly allied to *Dipsacæ*, from which they are distinguished by their looser inflorescence, sensible properties, want of albumen, and the absence of an involucrellum. They are more remotely related to *Rubiaceæ*. They are natives of temperate climates or elevated positions in both the Old and New World. They are more abundant in the north of Asia, Europe, and South America, than in Africa or North America. [VALERIANA; VALERIANELLA; SPIKENARD; NARDOSTACHYS.]

VALERIANELLA, a genus of Plants belonging to the natural order Valerianaceæ. This name is a diminutive of *Valeriana*, but was rejected by Smith, Hooker, and others, as not being in accordance with the Linnaean laws of nomenclature; and accordingly they have described its species under the Adansonian genus *Fedia*. De Candolle, Lindley, and other systematic botanists however still retain *Valerianella*, and confine the genus *Fedia* to a single species, the *F. cornucopie*.

Valerianella consists of annual herbs, with oblong or linear undivided toothed or pinnatifid leaves, and small white solitary or corymbose flowers. The limb of the calyx is toothed and permanent; corolla regular, 5-lobed; stamens 3; stigma nearly entire or trifid; fruit 3-celled, membranous, indehiscent. It includes about 25 species. Their distinctions are not easily made out, on account of the variable character of the different parts of the plant. De Candolle has divided them into four sub-genera, depending on differences existing between the structure of the fruit, which is sometimes 2-celled and sometimes 3-celled; but only one of the cells ever contains the seed. Varieties in the structure and form of the fertile and sterile cells are the foundation of De Candolle's sub-genera. Koch, in his 'Flora Germanica,' divides the German and Swiss species, which are only eight in number, into four sections, depending principally on the structure of the calyx. Four of the species are British, belonging to three of De Candolle's sub-genera.

V. olitoria, Common Corn-Salad, or Lamb's Lettuce, has globose, compressed, inflated, glabrous, oblique, 2-lobed fruit; the limb of the calyx almost wanting; the two sterile cells of the fruit in one produced by an incomplete dissepiment; the flowers capitate; leaves linear, and angles of stem scabrous. This plant is an annual, from four inches to a foot high. It is a native of Europe, in corn-fields and cultivated ground, and is found abundantly in such situations, especially in a light soil in Great Britain. In France and Germany it is much eaten as a salad, and is frequently cultivated for that purpose in this country.

The other British species of the genus are—*V. dentata*, Smooth Narrow-Fruited Corn-Salad; *V. mixta*, Sharp Rough-Fruited Corn-Salad; *V. eriocarpa*, Blunt Rough-Fruited Corn-Salad. All the species are innocuous, and may be eaten as salads.

VALLARIS, a genus of Plants belonging to the natural order Apocynaceæ. The species consist of a few twining shrubs, which are found in China, the Indian Islands, and the plains of India. Of these *V. Pergulana*, called *Echites hircosa* by Roxburgh, and common in the Indian Peninsula and Archipelago, is remarkable for its offensive goat-like smell; while *V. dichotoma*, indigenous in the North-Western Provinces, is remarkable for its agreeable odour. Its leaves are employed there as poultices.

VALLEY, LILY OF THE, a common name for the *Convallaria majalis*. This plant is too well known to need description. The genus *Convallaria* has a bell-shaped 6-parted deciduous perianth; a 3-celled 2-ovalled ovary; a blunt trigonous stigma; berry with 1-seeded cells; flowers jointed to the pedicel.

C. majalis, the Lily of the Valley, is about a foot high, with two ovate-lanceolate radical leaves. The flowers are racemose, nodding, pure white, globose, bell-shaped, and fragrant.

VALISNERIA, a genus of Plants belonging to the natural order Hydrocharaceæ. The species of this genus are all water-plants. They are dioecious: the male flowers are seated on a spadix; the corolla is monopetalous with three segments. The female flowers are included singly in a spathe, and are seated upon a spiral peduncle; the calyx is composed of a single leaf; the corolla is polypetalous; the capsules are 1-celled, many-seeded; the seeds parietal. Several species of *Valisneria* have been recorded as growing in Europe, Australia, and America. The economy of these plants is exceedingly interesting in a physiological point of view. They are plants growing at the bottom of the water, and yet the male and female flowers are separated, and the mode by which they are brought together affords a singular instance of adaptation. These plants generally grow in running waters, and thus render the difficulty of the contact of their flowers greater. This is effected by the elongated peduncles of the pistilliferous flowers reaching the surface of the water when the stamiferous flowers are floating along. The *V. spiralis* is found in Italy, in ditches near Pisa, and in the Rhône. There are two Australian species, and also an American and East Indian species. The latter is the *Hydrillus* of Dr. Hamilton, and is used in Hindustan under the name of Jangi, for the purpose of supplying water mechanically to sugar during the process of refining. [MOTIONS OF PLANTS.]

VALONIA. [QUERCUS.]

VALVATA. [PALUDINIDÆ.]

VALVE, in Botany, is a term applied to several parts of plants.

Its most common application is to the parts of debiscent fruits, these parts being in most cases the representative of the carpellary leaf.

VAMPIRE. We subjoin a cut of the common Vampire-Bat. [CHEIROPTERA.]

Skeleton of Vampire. (De Blainville.)

VAMPIRUS. [CHEIROPTERA.]

VANADIUM, a metal discovered in 1830 by Sefström, and named from Vanadis, a Scandinavian divinity; it has since been found by Professor Johnston: the former obtained it from the iron of Taherg in Sweden, and from the slag of the ore; the latter from a new mineral occurring at Wanlock Head, which he found to be Vanadate of Lead. The metal is obtained from the native Vanadate of Lead.

[LEAD.] **VANADURITE.** [LEAD.]

VANDA, a genus of Plants, the type of the tribe *Vandee*, of the natural order *Orchidaceae*.

VANDELLIA, a genus of Plants belonging to the natural order *Scrophulariaceae*. The species are natives of warm parts of the world, such as India, Birma, China, and Brazil, forming smooth or hairy herbs, with tetragonal stems; leaves opposite, usually toothed.

V. diffusa, a native of Brazil, thought to be found also in the peninsula of India. It is the *Cacaetia* of Pison, and described by Dr. Hancock as emetic, and its decoction as useful in fevers and liver complaints.

VANELLUS. [CHARADRIADÆ.]

VANGA. [LANIADÆ.]

VANGUERIA, a genus of Plants belonging to the natural order *Rubiaceae*. The species are few in number, of which the principal are *V. edulis* of Madagascar, and the Indian *V. spinosa*. Both species form small trees or shrubs, having ovate or oblong petiolate leaves, with lanceolate stipules, solitary on both sides. The fruit of *V. edulis* is eaten by the natives of Madagascar and of Mauritius, where it has been introduced, as well as into the peninsula of India. *V. spinosa*, the Mayna of the natives of Bengal, but which is found in many parts of the plains of India, is a distinct species, though united to the above by Sprengel in his 'Syst. Vegetabilium.' It is said to be also found in China. The fruit is eaten by the natives of India.

VANILLA, a genus of Plants, the type of Lindley's natural order *Vanillaceae*. The name is derived from 'vaynilla,' a diminutive of 'vayna,' which in Spanish signifies a knife or scissor-case, the fruit being long and cylindrical, and like the sheath of a knife. The species are generally supposed to be confined to Brazil, Guyana, and the West Indies, but several have been described by Schiede from Mexico. Species have also been found in Penang, Singapore, and Java.

The species of this genus are climbing plants, but are not epiphytic, as many of the *Ochidaceae*, although in climbing up trees they put forth roots as boldfasts, which are capable of absorbing nutriment for the plant when other modes of supply are cut off. The leaves are fleshy, sub-cordate at the base, and articulated with the stem; the stem is square, and frequently climbs to a height of 20 or 30 feet; the flowers are fleshy; the perianthium is articulated with the ovary, and frequently caliculated; the sepals and petals are nearly equal, conformed and free at the base; the labellum is entire, connate with the column, concave and barbed in the middle; the column is elongated and apterous; the anthers are terminal and opercular; the pollen-masses are two, bilobed and granulose; the fruit is siliqueform, fleshy, and dehiscing at the side; the placentæ, from 3-6, covered with seeds; the seeds are globose, and covered with a closely adnate testa.

Lindley enumerates eight species as belonging to this genus, two of which have been found in Asia and six in America. The fruits of most of them are aromatic, and on this account have formed a considerable article of commerce from their consumption as a luxury.

V. aromatica, Aromatic Vanilla, has ovate-oblong acuminate sessile leaves; perianth campanulate, with five undulated acuminate laciniae; the labellum acuminated, cucullate at the base, with an elevated naked middle lobe. This species is the *Epidendrum Vanilla* of Linnæus, and is a native of Brazil, and was supposed at one time to yield all the vanilla of commerce. Under this name have been included two or three species of *Vanilla*, one of which is probably the only species that yields vanilla. The vanilla which is added to chocolate, custards, and

many kinds of confectionary, to give them a pleasant flavour, is the produce of *V. aromatica*. [VANILLA, in ARTS AND SC. DIV.]

Vanilla aromatica.

1, branch with flowers; 2, branch with fruit; 3, section of fruit showing the three placentæ and indefinite seeds.

VANILLA'CEÆ, a natural order of Plants, formerly regarded by Lindley as a distinct order, but now embraced in the sub-order *Arethuseæ*, of the order *Orchidaceae*.

VARANIDÆ, *Varanians*, a family of Lizards, designated by Messrs. Duméril and Bibron as *Platynote* or *Broad-Backed Saurians*, and thus characterised by them:—Body very much elongated, rounded, and without a dorsal crest, supported on strong legs and feet, with distinct and very long but unequal toes. Tail slightly compressed, at least twice longer than the trunk. Skin furnished with enched scales, which are tuberculous, projecting, rounded upon the head as well as upon the back and sides, always distributed in rings or circular bands, parallel under the belly and round the tail. Tongue protractile, fleshy, similar to that of the serpents, that is to say, capable of elongation and of being withdrawn into a sheath, narrow, and flattened at the base, and deeply divided and separated into two points which can be divaricated as in the Ophidians.

Linnæus arranged these Saurians under the great genus *Lacerta*. Daudin separated the larger portion of the species under the generic appellation of *Tupinambis*.

Dr. J. E. Gray, in his 'Synopsis' (1827), arranged under his family *Varanidæ* the genera *Varanus* and *Dracena* of Merrem, which he very well characterised. No such family as the *Varanidæ* appears in Dr. Gray's Table, published in the British Museum Synopsis (1842), and the British Museum Catalogue (1845); but the *Monitoridæ* (which are the first family of the *Leptoglossæ*, the first group of his *Sauria*) consist of the genera *Psammosaurus*, *Monitor*, *Polydactylus*, *Empagusia*, and *Hydrosaurus*. [MONITORIDÆ.]

Next to the *Crocodylidae*, the *Varanidæ* attain the greatest size of any of the Saurians; indeed Herodotus, Ælianus, and others regarded them as terrestrial crocodiles.

The *Varanidæ* are divisible into two distinct groups: the eminently terrestrial group, whose abode is far from the waters, in desert and sandy places; and the aquatic group, consisting of those which inhabit the banks of rivers and lakes.

The first have the tail entirely conical and nearly rounded, and it would appear at first sight to be useless, if not in the animal's way: but as Nature makes nothing in vain, Wagler's notion that it acts as a necessary counterpoise to the trunk is probably, so far as it goes,

correct. The multitudinous bones which form the tail of the second are very well developed, particularly in their transverse processes, and offer strong points of attachment for the muscles: the upper and lower apophyses are comparatively greatly increased. Compressed throughout its entire length, this tail becomes a powerful organ of motion when the animal is in the water, particularly as it is often surmounted with a crest formed by one or two rows of flattened scales, a fit propelling oar for the body rendered buoyant by the air with which the lungs are filled.

On land they run with rapidity, but their motion is always serpentine, a mode of progression due to their long tail, which helps to push them forward, and aids them in their leaps upon the prey which they pursue.

Their food consists of animal matters, and especially large insects, such as *Blatte*, locusts, crickets, and beetles. It is asserted that they hunt after the eggs of birds and crocodiles, and that chameleons, small tortoises, and fish have been found in their stomachs. M. Leech-nault de Latour relates that they unite on the banks of rivers and lakes to attack quadrupeds which come to quench their thirst, and that he has seen them attack a young stag as he attempted to swim across a river, in order to drown him. He even declares that he found the thigh-bone of a sheep in the stomach of one which he dissected.

Such are the animals which in certain parts of their organisation come nearest to the great extinct Saurians of old. If the habits ascribed to these Varanians bore any relation to those of the great carnivorous Saurians now swept away from the face of the earth, we should have in those annihilated giants no bad representatives of the dragons of our wildest legends.

Geographical Distribution.—The family of Varanians, as modified by Messrs. Duméril and Bibron, exist in all parts of the world, with the exception of Europe.

America claims one only,—that on which the genus *Heloderma* is founded.

In Asia there are four *Varani* properly so called; three in Africa; and four in Oceania. Of these four, two have been observed in Australia, one in the isles of the Papuan Archipelago, and the fourth in the Isle of Timor.

Messrs. Duméril and Bibron state that the locality of one species, *Varanus albigularis*, is unknown, but Dr. Smith obtained it in South Africa; it thus makes a fourth African species.

The species of the genus *Varanus*, or *Haranus*, are distinguished by the form assumed by the scales upon the back.

1, Head of *Varanus nebulosus*; 2, dorsal scales of the same; 3, dorsal scales of *Varanus niloticus*; 4, dorsal scales of *Varanus picnotii*.

V. albigularis is an example of the terrestrial species. It is the *Tupinambis gularis* of Daudin; *Varanus ornatus*, Merr.; *Tupinambis albigularis*, Kuhl; *Polydardalus albigularis*, Wagl., and *Monitor albigularis* of Gray. It is a native of Africa.

Varanus albigularis. (Smith.)

V. Bellii is an example of the aquatic species. It is a native of Australia.

Varanus Bellii.

Heloderma horridum is another aquatic species. It is a native of Mexico, where there is an erroneous but general belief that the bite of this species is fatal.

Head of *Heloderma*.

Heloderma horridum.

VARANUS. [MONITORIDÆ; VARANIDÆ.]

VARI, Buffon's name for the *Lemur Macaco* of Linnæus.

VARIETIES, in Botany, are groups of individual plants subordinate to species. The character of the Species is found in its capability of reproducing by seed a plant which is more like itself than it is like anything else; and this under all circumstances in which the offspring is capable of being produced. The Variety differs from the Species in

points of structure which are developed only under certain circumstances, and which are not essential to the species. This may be illustrated by an example—as, for instance, the common apple (*Pyrus malus*). If the seeds of the wild apple, or any of the cultivated varieties of apples, are sown under any circumstances, the plants that spring from these seeds will, in the great mass of their characters, be more like all other apple-trees than they will be like pear, plum, or any other trees. This then illustrates the idea of a species. If, on the other hand, the seeds of some of the sorts of apples, known under the names of Golden Pippin, Nonpareil, &c., be sown under different circumstances from that in which the plant from which they are taken was grown, the plants produced will differ in many respects from their parent in the characters that constitute the variety, but not in those of the species. The characters on which the definition of a species is founded ought to be such that no circumstances can alter them, whilst the essence of a variety consists in its having characters which are altered and produced by circumstances. Buds propagate the character of the variety, but seeds continue the species.

The natural varieties of plants are nothing like so numerous as those which arise from cultivation. Almost the entire object in view in the kitchen- and fruit-gardens is the developing of some property in plants which they do not exhibit in their natural state, and this is mostly attended with a corresponding change of structure. All the varieties of apples are produced by cultivation from the common crab (*Pyrus malus*); all the pears from *Pyrus communis*; the cherries from *Prunus Cerasus*; peaches, apricots, nectarines, from *Amygdalus Persica*; and plums from the *Prunus domestica*. The same is true of vegetables: all the varieties of cabbages are produced by cultivation from the same species; so also with turnips, potatoes, radishes, &c. This is also the case with flowers: the great majority of tulips, roses, anemones, *Ranunculi*, &c., found in gardens, are the result of changed characters dependent on cultivation. Although many of the varieties of fruits, vegetables, and flowers, retain the same names for a great length of time, there is nothing permanent in their characters but those which belong to the species.

VARIOLARIA, a genus of Plants belonging to the natural order of *Lichenes*. This name is derived from 'variola,' because the apothecia resemble the pustules of small-pox. The thallus of the plants belonging to this genus is crustaceous, membranaceous, adnate, spreading, uniform. The apothecium is a suborbicular scutelliform cup, formed of the thallus, and filled with a powdery or flocculose substance which covers an immersed waxy disc containing imbedded thecae. The species are of an ash-gray or white colour, and are found on the bark of the trunks of various trees, on rocks, walls, or on the ground. About 13 species are found in Great Britain.

V. faginea, the Bitter-zoned Variolaria, has an orbicular crust, surrounded by a zonate border of various colours; the apothecia are very abundant, convex, with an obsolete border, and filled with a snowy white powder. This is one of the species included in the *Lichen fagineus* of Linnæus. It is common on the bark of trees, especially of old beech-trees, and on pales. This species is distinguished from all others of the genus, as well as of the order, by its intensely bitter taste. It is for this reason that Turner and Borrer have separated the *V. discoida* from this species, although it has only a very slight structural dissimilarity; but it has no bitter taste at all. Braconnot found that the *V. faginea*, as well as several other crustaceous lichens, contained oxalic acid. The quantity yielded by 100 parts of this plant was 29.4 of oxalic acid, combined with 18 of lime. It is at the present time employed in France, on a very extensive scale, for the purpose of obtaining oxalic acid.

V. lactea, Milky-White Variolaria, is one of the lichens that are collected for the purpose of being used in dyeing.

V. globulifera, Vesicle-Fruited Variolaria, is found only rarely, growing on the bark of old oaks and beech-trees. It was gathered by Dr. Sibthorp in Greece; and, on account of the form of the reproductive organs, is the most remarkable-looking species of the genus.

V. vitiligo, Leprous Variolaria, has an elliptical, very thin, almost filmy, whitish crust, with very numerous, minute, oblong, confluent apothecia, having a very narrow elevated margin, and containing a lead-coloured powder. This is one of the most common species of the genus, and is common on old rails and gate-posts, giving them the appearance of having been imperfectly daubed over with white paint.

VARNISH-TREE. [MELANORRHEA.]

VARVICITE. [MANGANESE.]

VASCULAR TISSUES. [TISSUES, VEGETABLE.]

VASCULARES, in Botany, applied to the two principal classes of plants, *Exogens* and *Endogens*, on account of their highly-developed vascular tissues, in opposition to the class of *Acrogens*, the tissues of which are principally cellular, and hence they are called *Cellulares*. [*EXOGENS*; *ENDOGENS*; *ACROGENS*.]

VATERIA, a genus of Plants belonging to the natural order *Dipterocarpaceæ*. It is characterised by having the calyx 5-cleft; segments at length reflexed; petals 5, oval, emarginate, twisted in the bud; stamens 40 to 50, short, inserted between the petals and the base of the germ; anthers long, linear; capsule 3-valved, 1-celled, and 1-seeded; cotyledons stalked.

The species are two in number, *V. Indica*, which grows all along the

NAT. HIST. DIV. VOL. IV.

Malabar coast and in Canara; and *V. lanceafolia*, which is common in Silhet. Both species form large trees with entire smooth coriaceous leaves, and terminal panicles of white flowers; and both are valuable not only as timber-trees, but for yielding valuable, almost unique products. *V. Indica* grows to the height of about 60 feet, and yields valuable timber, which is much employed in ship-building, and is not liable to be attacked by the teredo. When the bark is wounded, a pellucid, fragrant, acrid, bitter, resinous fluid exudes, which in the rays of the sun becomes yellow and fragile like glass. This resin is well known in commerce, and is usually called Copal in India, but when imported into England receives the name of Gum Anime. The fluid resin also makes a good varnish, which is called Pundum, or Liquid Copal; on the Malabar coast it is often called Piney Varnish, and the tree Piney Varnish-Tree, or Piney Marum. The dry resin, boiled with more or less oil, is used for the purposes of tar and resin; it is also employed by the natives instead of frankincense. Besides these, another very valuable product is yielded by this tree, and that is a fatty substance, which is known by the name of the Piney Tallow, or Vegetable Tallow, of Canara. This is obtained by boiling the seeds, when the fatty substance floats to the surface, and on cooling down becomes of the consistence of tallow. In colour the different specimens vary from pale yellow, or fawn, to perfect white. Its general properties, such as its hardness, colour, combustibility, and fusibility, place it between wax and tallow; but it is far superior to the latter, having no disagreeable smell, either when burning or at common temperatures.

V. lanceafolia is the other species, which was described by Dr. Roxburgh from Silhet, where it is called Moal. Like its congener, this also exudes a clear liquid from wounds, &c., in the bark, which soon hardens into an amber-coloured resin. From this the natives distil a dark-coloured and strong-smelling resin called Chooa, and Chova and Gond by the Brahmans, who use it as incense.

VAUCHERIA, a genus of Plants belonging to the inarticulate *Algae*, named after Professor Vaucher of Geneva. This genus belongs to the tribe *Siphonæ*, and was formed by De Candolle from Vaucher's genus *Ectosperma*. The fronds or filaments are aggregated, tubular, continuous, capillary, and coloured by an internal green coloured mass. The fructification consists of dark green homogeneous vesicles, which are attached to the filaments. The species are found in pools and ditches and stagnant waters, on damp ground, and on the mud of salt-water rivers and in the sea.

V. dichotoma, Large Dichotomous Vaucheria, has dichotomous filaments, with solitary globose sessile vesicles. This is one of the most common of the species, and is found, in spring and autumn, in pools and ditches of fresh water, and Mr. Berkeley has found a variety in the sea. It is one of the largest of this genus, its filaments being often more than a foot long, and filling up the ditches on account of their number.

V. Dillwynii, Dillwyn's Vaucheria, has branched flexuose filaments, with globose lateral sessile vesicles. This species is common on the ground in damp situations, forming a thin intricate fleece of a green colour.

V. clavata, Clubbed Vaucheria, has short filaments terminating with a vesicle, which contained the sporules. This species does not appear to be an inhabitant of Great Britain. It inhabits ditches of clear water, and is interesting on account of the observations made upon it by Unger. Whilst examining this plant, he found that the vesicular summits had the power of contraction, and that by this process they expelled the contained sporules, which after their expulsion ascended to the surface of the water. "As I continued my observation," says Unger, "I happened to look at the surface of the water, and was not a little astonished to find it covered, especially towards the side of the vase, with minute globules, unequal both in colour and size. Many of them swam freely here and there, moving at their option in one way or another, retiring and approaching one another, gliding round globules that were motionless, stopping and again setting themselves in motion, exactly like animated beings. Conjecturing the identity of the green globules that possessed motion with those that had none, I immediately began to examine whence these infusory animalcules derived their origin, and what relation they bore to the green globule and the fructification of the *Conferva*. The next day I perceived a great number of globules aggregated around the bubbles of gas disengaged from the *Conferva*, and floating at the surface. There were some of them of a dark green colour, and either round or elongated; others more transparent, humid, and with one or two appendages diverging from or at right angles with each other: these were evidently plants in a state of germination. Other globules again were oval, very dark at one extremity, and almost transparent at the other; these swam about freely. Within the space of one hour I succeeded in tracing not only the diminution of vitality and death of the *Infusoria*, but also the subsequent development of the dead animals into germinating plants, in such a manner as to establish the truth of the fact." ('Mag. of Nat. Hist.,' vol. i.) There are 9 species of the genus *Vaucheria* found in Great Britain.

VAUQUELINITE. [CHROMIUM; LEAD.]

VEGETABLE BUTTERS. [BUTTERS, VEGETABLE.]

VEGETABLE IVORY. [PHYTELEPHAS.]

VEGETABLE KINGDOM. This term is applied collectively to

the various forms of Plants, as the terms Animal and Mineral Kingdoms are applied to Animals and Minerals. The distinctions which are supposed to limit these three kingdoms are treated of in the article ANIMAL KINGDOM. We shall here speak of the uses, general features, and distribution of Plants.

The Vegetable Kingdom performs important offices in the economy of creation. It stands between the mineral and animal kingdoms, disposing and arranging the elements of the first in order to fit them for the purposes of the last. Each of the three kingdoms of nature is composed of matter as its basis; but the animal kingdom directly appropriates no portion of the elements of the inorganic world to its uses, but derives them all from the vegetable kingdom. The researches of chemists show that the proximate principles of animal bodies are identical with those of vegetables, and that consequently, as these principles do not exist in the inorganic kingdom, they must have been formed in plants. Thus we must regard the vegetable kingdom as one vast chemical laboratory, in which the food of animals is being prepared. Without vegetables animals would perish, and although some animals live on the flesh of others, yet that flesh is always originally derived from the vegetable kingdom. The proximate principles of plants are not numerous, and are composed of hydrogen, oxygen, nitrogen, and carbon; those containing nitrogen are directly appropriated by animals to the formation of their tissues, whilst those containing no nitrogen are either consumed in generating animal heat or deposited in the form of fat. When animal bodies cease to exist, their tissues become resolved into their primitive elements, a process which is constantly going on in animal bodies during life. These elements, in the state of various compounds, are carried off into the atmosphere when gaseous; or assist in forming the soil on the surface of the earth when solid. The principal compounds which are thus generated are carbonic acid and ammonia; and if accumulation of these gases took place to any extent in the atmosphere the consequences would be a cessation of vitality in both the animal and vegetable kingdoms; but here again plants perform an important office, for these very compounds combined with water are the principal sources of the elements which plants elaborate into so many secretions necessary to the existence of animals. There is thus a relation established between the animal and vegetable kingdoms, of which man has extensively availed himself in the application of manures to the artificial production of food. In this relation too are involved the laws of the production of plants for food in communities with circumscribed districts, to the investigation of which comparatively little attention has been given.

In addition to supplying food and purifying the atmosphere for animals, the vegetable kingdom is made use of extensively by man. The larger forms of plants are used for the building of houses and ships, the construction of furniture, and a thousand implements necessary in the arts of life. The various secretions of plants, their oils, resins, acids, neutral and alkaline principles, all exert a powerful agency on the human system, and are employed for the purpose of controlling, changing, and interrupting the diseased actions to which man is subject. Another large class of plants furnishes him with luxuries, as tobacco, tea, coffee, spices, perfumes, and fruits of various kinds; and to these must be added fermented liquors, which are all produced from the fermentation of the saccharine juices of plants. A great part of the clothing of man is the produce of the vegetable kingdom: cotton, flax, and hemp are of vegetable origin, and when the fabrics which are made from them are worn, they are mostly coloured with the secretions of the turmeric, indigo, orchil, catechu, and others.

Climate is also modified by the vegetable kingdom. The presence of thick forests intercepts the rays of the sun, and the earth has a lower temperature in consequence. On the other hand, the heat of the surface of the earth is changed by the difference of radiating power between plants and the soil on which they grow. The constant absorption and exhalation also of a large body of plants will affect the humidity of the atmosphere according to the circumstances in which they may be placed. Another consequence of the existence of plants is the production of malaria during their decay. There is perhaps no fact better proved than that decaying vegetable matter is the source of the most dreadful pestilences that affect human beings. The direct agency by which this is effected is unknown; it is called malaria, and is alike produced by decaying plants in the swamps of Africa, the jungles of India, the savannahs of America, and the ditches of Europe. No part of the world where vegetables are produced is free from its influence; and even in large cities, perhaps the only places susceptible of being made a refuge from its scourge, needless accumulations of decomposing vegetable matter are allowed to become the source of disease and death.

Plants also give peculiar features to the surface of the earth, and by their distribution the life of the animal kingdom is regulated. Although each plant appears to have a special constitution, by which its existence in particular parts of the earth is determined, certain external agents exercise a controlling influence, and to these we shall now refer.

Of the agents that determine the distribution and character of plants none have more influence than light. Wherever plants have a large supply of light, there will the vegetation be prolific, and all the secretions of plants will abound. It is by this agent that the functions

of absorption, exhalation, and the decomposition of carbonic acid and other compounds are effected by plants. It is, in fact, a powerful stimulant of vegetation, and it acts as all stimulants do on organic bodies. If a plant is withdrawn from its influence, it becomes weak, its tissues soften and are filled with water, and few or no secretions are deposited; on the contrary, if plants are supplied with continued light, they become overstimulated, they decompose carbonic acid rapidly, and become stunted in their growth on account of the rapid development of solid secretions. The influence of this agent is seen remarkably in the vegetation of the surface of the earth. In the tropics the direct rays of the sun are felt by plants, and under their influence a prolific and gigantic vegetation is developed, but this arises from the alternate withdrawal and presence of this agent during every 24 hours, and as this is constantly the case, vegetation remains the same throughout the year. On the other hand, at the poles, only the oblique rays of light are felt, and consequently its influence is comparatively feeble. The gradations of vegetation may be seen, under the influence of this agent, in passing from the tropics to the poles. From the magnificent baobabs, banyans, and palms of the tropics, we pass through the regions of oaks, elms, and firs, of temperate climates, till in polar regions the only representatives of trees are a few hrambles, and the majority of plants are mosses and lichens.

Another agent is heat. By some this has been supposed to have more influence than light on the distribution of plants, but it is difficult in nature to separate its influence from that of light, since it is derived from the same source at the same time. However experiments on a large scale are constantly going on in European hothouses, in which it is proved, that although tropical plants be supplied with their natural temperature, nothing will make up for the want of light, and many of them seldom produce their flowers and less seldom their fruit, and after a languishing existence soon die. The influence of heat on vegetation is seen in those climates where there is a great difference of temperature between summer and winter. The plants of such districts that live throughout the winter are so constructed that they are enabled to bear the cold of winter. They have frequently thick barks, in which are deposited resinous secretions, and are thus enabled to withstand the decrease of temperature. It is also found, for this reason, that those plants which thrive in hot summers are best adapted to withstand the cold of winter, on account of the greater amount of solid secretions deposited in their bark, and many plants which flourish in districts where there are hot summers and severe winters will perish in climates where the extremes of heat and cold are not so great. Thus many plants will grow around Paris, where the extremes of heat and cold are great, which will not grow around London, where these extremes are less; and the same holds good with regard to London and Edinburgh, and the floras of the south of England and the north of Scotland afford abundant evidence of the truth of this position.

Water, as an agent affecting vegetation, must be regarded in two points of view: first, as existing in the atmosphere as vapour, modifying temperature, and controlling the function of exhalation and absorption in plants; and, secondly, as existing on the surface of the earth in the form of oceans, rivers, lakes, swamps, &c. The composition of the waters of these last also, or rather the substances which may be dissolved or suspended in the water, produce considerable effect upon vegetation. Many *Orchidaceae* are only found in the humid forests of the tropics. The vegetation of seas and lakes varies with the circumstances of the ingredients they contain in solution, and with the comparatively restless or quiet condition of their waters. Swamps produced by overflows of the sea produce different plants from those produced by accumulations of fresh waters from mountain sides.

The characters of the soil influence the vegetation of particular districts. The previous agents exert an influence on vegetation which is most evident in the characters of the great mass of plants of a district; but the soil produces effects on almost every individual plant. The influence of soil arises from its mechanical character and chemical composition. The mechanical character of most importance is its amount of disintegration. Some plants, as lichens, grow on the surface of rocks and large stones, and are not found in districts where these are not present. Some require a loose soil for the free passage of their roots, and are only found growing in sands. Others again will only exist in tenacious soils, and are found growing in clays. The mechanical character of soils also greatly influences their relation to the absorption and radiation of heat, and thus affects the temperature of the soil.

The last influence to which we shall refer is the atmosphere. Chemically it remains in its great constituents, oxygen and nitrogen, constantly the same. But the quantity of the vapour of water which it contains, and whatever salts that vapour may be capable of containing, cause it to vary much. The influence of these agents in the air however is not different from the same in the soil. The agitation of the air by constant winds has often an important influence on vegetation, and the barren hills and coasts of many countries are owing to the impossibility of plants withstanding the influence of strong winds. The density of the atmosphere is a point of importance, and seems to disturb the relation between elevation and latitude.

Several methods have been proposed by De Candolle and other botanists for giving an idea of the distribution of vegetation over the

surface of the globe. In the following remarks we have followed that of Professor Schouw, in his 'Notes for a Course of Lectures on the Distribution of Plants.'

1. Region of Saxifragas and Mosses, or the Alpine Arctic Flora: temperature $1^{\circ}75'$ to 41° Fahr. This corresponds with the hyperborean region of De Candolle and other writers, and comprehends all countries within the polar circle, namely, Lapland, the north of Russia and Siberia, Kamtschatka, Labrador, Greenland, and Iceland, and also part of the Scottish and Scandinavian mountains, as well as the mountains of the southern and central parts of Europe, which have sufficient elevation to possess an alpine vegetation. This region is characterised by the abundance of mosses and lichens, and of the families *Saxifragaceae*, *Gentianaceae*, *Alsinaceae*, *Salicaceae*, and *Cyperaceae*. There is an entire absence of tropical families, and only a few plants of the temperate zone. The beech and fir occur in forests, or there is a destitution of trees. Annuals are also scarce, and the blossoms of the flower are larger in proportion to the root of the plant, and of a pure colour.

2. Region of the *Umbelliferae* and *Cruciferae*: temperature $27^{\circ}5'$ to $56^{\circ}75'$. This comprehends the whole of Europe, except those districts which belong to the preceding region, from the Pyrenees, the mountains of the south of France, of Switzerland, and the north of Greece, to the greater part of Siberia, and the country about Mount Caucasus. This region is particularly distinguished from that of the same parallel in North America by the presence of cruciferous and umbelliferous plants. It is not easily distinguished from the next region, but the *Fungi* abound more, and it approaches the last region in the abundance of *Cyperaceae*. Nearly all its trees are deciduous, and its meadows are exceedingly flourishing. There is a division of the *Compositae*; the plants belonging to the Cichoraceous division of that order being found in the northern districts, whilst those belonging to the Cyarocephalous are found in the south of it. The predominating trees are the Scotch Fir, the Alder, the Beech, the Birch, the Poplar, the Elm, and Lime. The shrubs are the Heaths, the Sloe, &c. The principal cultivated plants are the Wheat, Barley, Oats, Maize, Potatoes, &c.; Apple, Pear, Gooseberry, Currant, Vine, Strawberry, Cucumber, Melon, the Cabbage, Turnip, Peas, Beans, and other forms of *Leguminosae*; Carrots, Hops, Hemp, Flax, &c.

3. The Region of *Labiatae* and *Caryophyllaceae*, or the Mediterranean kingdom: temperature $54^{\circ}5'$ to $72^{\circ}5'$. This includes the region of the Mediterranean Sea, limited on the north by the Pyrenees, the Alps, the Balkan, the Caucasus; on the south by the Atlas and the deserts of North Africa; on the east by Taurus. It contains more or less of the orders belonging to the last region; but *Labiatae*, *Caryophyllaceae*, *Boraginaceae*, *Cistaceae*, and *Liliaceae* abound. A few tropical plants now and then appear amongst them, belonging to the orders *Palmaceae*, *Terebinthaceae*, and *Lauraceae*. *Solanaceae* and *Leguminosae* are more abundant than in the last, evergreens increase, and the vegetation never entirely ceases; but verdant meadows are more rare than in the last. Madeira, Azores, and the Canary Islands, belong to this region, and their Flora approaches to that of tropical Africa. The cultivated plants are similar to the last, to which are added the Olive, Orange, Lemon, Mulberry, Fig, Rice, &c.

4. The Region of *Asteraceae* and *Solidaginaceae*, or North North-American kingdom: temperature $9^{\circ}5'$ to 59° . It embraces North America from the southern limits of the first kingdom to 36° N. lat. There are a greater number of *Coniferae* than in the second kingdom, and there are but few *Umbelliferae*, *Cruciferae*, *Cichoraceae*, and *Cynarophalaceae*. There is but little cultivation: where there is any it resembles that of the second kingdom. Whortleberries, Oaks, Firs, Michaelmas Daisies, and Golden Rods are its great characteristics.

5. The Region of *Magnoliaceae*, or Southern North-American kingdom, between 36° and 30° N. lat.: temperature 59° to $72^{\circ}5'$. There is here an approximation to tropical vegetation, as seen in the frequent appearance of the genera *Canna*, *Chamærops*, *Yucca*, *Zamia*, *Laurus*, *Bignonia*, *Passiflora*, *Cassia*, *Sapindus*, &c. There are comparatively few plants that are characteristic of the two preceding kingdoms. The Magnolias predominate, and are accompanied with other genera bearing broad shining leaves and large flowers. The cultivated plants are those of the third region, with the exception of the Olive: Rice is more abundant, and in the southern districts the Sugar-Cane is grown.

6. The Region of *Camellias*, and *Celastraceae*, or Chino-Japanese kingdom. It embraces Japan and Northern China from 30° to 40° N. lat.: temperature $54^{\circ}5'$ to 68° . Too little is known of this region to enable us to state positively what are its characteristics. Its vegetation is more tropical than European. With Zamas, Ginger, Bananas, and Custard-Apples, are found Buckthorns and Honeysuckles, thus giving this region a mixed character. Its cultivated plants, in addition to those of the previous regions, are the *Cycas* for Sago, the Tea-Plant, the Caladium, &c.

7. The Region of *Zingiberaceae*, or Indian kingdom: temperature $65^{\circ}75'$ to $81^{\circ}5'$. This includes the Indian peninsula east and west of the Ganges, together with the islands between India and Australia. Tropical orders are numerous in this region, as *Palmaceae*, *Araceae*, *Euphorbiaceae*, *Bignoniaceae*, *Buttneriaceae*, &c. Very few plants belonging to *Cyperaceae*, *Coniferae*, *Labiatae*, *Rosaceae*, *Ranunculaceae*, or *Cruciferae* are seen. The trees never lose their leaves, and produce large magnificent flowers, and are covered frequently with climbing and

parasitical plants. Ginger, Zedoary, Cardamom, Arrowroot, Catechu, Cassia, Cinnamon, Caoutchouc, Tamariads, Sago, Rice, Cocoa-Nut, Coffee, Cubebs, Cloves, Pepper, Oranges, and Gamboge, are the cultivated and natural productions of this prolific region.

8. The Region of the Himalaya: temperature $36^{\circ}5'$ to $65^{\circ}75'$. It includes the highlands of India, or the mountain terraces lying on the south of the Himalayan range, Kumaon, Nepal, Bootan, having an elevation of from 4000 to 10,000 feet. The tropical forms of the last kingdom decrease manifestly here, such as *Scitaniaceae*, *Palmaceae*, *Cycadaceae*, &c. European forms are not unfrequent, as *Cyperaceae*, *Amentaceae*, *Coniferae*, *Primulaceae*, *Rosaceae*, *Cruciferae*, &c. The Ferns and *Orchidaceae* are abundant. The cultivated plants are the corn and fruit of Europe, varying with more tropical productions according to elevation.

9. The Region of *Polynesia* includes the islands between Hindustan and Australia, and has a temperature from $65^{\circ}75'$ to $83^{\circ}75'$. This region is similar to the Indian kingdom, and is sometimes included in it. The cultivated plants, in addition to those of the Indian kingdom, are the Bread-Fruit-Tree, the Nutmeg, the Camphor-Tree, and the Cotton-Tree.

10. The Region of Java is little known, and has a vegetation probably similar to the Himalayan region.

11. The Oceanic Region, or South Sea Island kingdom, includes all the islands of the South Sea within the tropics, and has a temperature of $72^{\circ}5'$ to $81^{\circ}5'$. The flora of these islands is poor, and approximates more closely to that of Asia than to that of Africa, and has some relation to that of Australia. The bread-fruit is the most characteristic production of these islands, but is not confined to them.

12. The Region of *Balsomodendra*, or the Arabian kingdom, includes the south-westerly mountainous part of the Arabian peninsula. The temperature cannot be stated, but the character of its vegetation is generally tropical, assuming the forms of that of India. The cultivated plants are also principally those of India.

13. The Desert Region includes North Africa south of the Atlas, and the Mediterranean Sea between 15° and 30° N. lat., and the northern part of Arabia. The mean temperature is $72^{\circ}5'$ to 86° . It has necessarily a very poor flora, having but few even characteristic genera. It is only cultivated in the oases, where the *Phoenix dactylifera*, the *Sorghum vulgare*, with Wheat and Barley, and some of the fruits of Europe and India, constitute the prominent plants.

14. The Region of tropical Africa includes Africa from 15° N. lat. to the tropic of Capricorn. Temperature $72^{\circ}5'$ to 86° . This flora is neither rich nor rare; it abounds in *Leguminosae*, *Rubiaceae*, and *Cyperaceae*. The *Adansonia* is a characteristic genus.

15. The Region of *Cacti* and *Piperaceae* includes Mexico and South America to the Amazon River, and to a height of 5000 feet above the level of the sea. Temperature 63° to $83^{\circ}75'$. The orders which characterise this region are *Bromeliaceae*, *Piperaceae*, *Passifloraceae*, and *Cactaceae*. The orders which are mostly tropical are here less numerous, whilst extra-tropical orders are more abundant. The most abundant genera are *Phyllephas*, *Kunthia*, *Thouinia*, *Theobroma*, *Guazuma*, &c. The cultivated plants of this district are the Maize, *Sorghum vulgare*, *Dioscorea alata*, *Convolvulus Batatas*; also the Plantain, Cocoa-Nut, Pine-Apple, Tamarind, Cacao, Vanilla, Coffee, Sugar, Tobacco, Cotton, &c.

16. The Region of the Mexican Highlands includes the mountains of Mexico above 5000 feet elevation. Temperature from $65^{\circ}75'$ to $79^{\circ}25'$. In this district the more tropical forms of vegetation, as the Tree-Ferns, the Palms, Passion-Flowers, Euphorbiums, and Pepper, decrease, or altogether disappear. The extra-tropical forms are more numerous, as the Willow, Oak, Fir, Cypress, Sage, Horehound, Whortleberry, Heath, and various forms of *Umbelliferae*, *Rosaceae*, *Caryophyllaceae*, *Cruciferae*, and *Ranunculaceae*. The cultivated plants are the Maize, the European *Cerealia*, and fruits. In the highest mountain-ranges the vegetation has an alpine aspect.

17. The Region of *Cinchonaceae*. This embraces the Andes from 5000 to 9000 feet in elevation, and between 20° S. lat., and 5° N. lat., having a temperature from 59° to 68° . The extra-tropical forms become very frequent in this region, and only a few tropical forms remain. Some of the most common genera are the *Cinchona*, *Gaylussacia*, *Loasa*, *Lilaea*, *Cervantesia*, &c. The cultivated plants are very seldom tropical. Maize and coffee are sometimes grown, with European *Cerealia*, and fruits, Potatoes, and *Chenopodium Quinoa*.

18. The Region of Escallonias and Calceolarias includes the Andes at more than 9000 feet above the level of the sea, between 20° S. lat. and 5° N. lat. Temperature $34^{\circ}25'$ to 59° . Tropical plants almost entirely disappear in this region, only now and then a straggler appearing; whilst the forms which distinguish the colder and polar regions become frequent, such as the Lichens, Mosses, Sorrels, Plantagos, Gentians, Currant, Brambles, &c. The most prevalent orders are the Grasses, Heaths, and *Synantheraceae*. There are no large trees, and a great many shrubs.

19. The West Indian Region, including the West India Islands, with a temperature of 59° to $79^{\circ}25'$. The vegetation of these islands bears the same relation to the continent which that of the Polycasian islands does to China. It is chiefly distinguished by the greater quantity of Ferns and *Orchidaceae*. The cultivated plants are the same as those of Mexico.

20. The Region of Palms and *Melastomaceæ*, or Brazilian kingdom, including Brazil, or South America, on the east of the Andes, between the equator, and the tropic of Capricorn; temperature 59° to 83.7° . This region is remarkable for the number of its genera and species, the size of individual trees, the dense forests, and the numerous climbing and parasitical plants. Vegetation seems here to attain its greatest activity and energy. The orders which abound most are *Palmaceæ*, *Hamadoraceæ*, *Gemeraceæ*, *Melastomaceæ*, *Sapindaceæ*, and, altogether confined to this region, *Vochyaceæ*. The cultivation is very similar to that of Mexico.

21. The Region of Woody *Compositæ*. In South America, on the east of the Andes from the tropic of Capricorn to 40° S. lat.: temperature 59° to 74.75° . There are but few tropical plants in this region, and extra-tropical plants, especially European forms, are abundant, more than half being common to this region and Europe. The Woody *Compositæ* abound. This region consists chiefly of plains (pampas), which for hundreds of miles present almost the same vegetation, consisting chiefly of Thistles and Grasses. Wheat, the Vine, and the Peach, are cultivated.

22. The Antarctic Region includes the south-westerly part of Patagonia, Tierra del Fuego, between 50° and 55° S. lat.: temperature 41° to 47.5° . In this region there are no tropical plants, and its vegetation resembles in a great measure the North-European flora (region 2). In some of the genera there is an approach to the South African and Australian flora.

23. The Region of *Stapelia*s and *Mesembryanthemum*s. This embraces South Africa from the tropic to 35° S. lat.: temperature 54.5° to 72.5° . The vegetation of this region is not luxuriant, but it is very rich in forms. There are no dense forests nor climbers, but many succulent plants. The orders *Restiaceæ*, *Iridaceæ*, *Proteaceæ*, *Ericaceæ*, *Ficoidaceæ*, *Bruniaceæ*, *Diosmaceæ*, *Geraniaceæ*, *Oxalidaceæ*, and *Polygalaceæ*, embrace its characteristic vegetation. On the sandy coasts the genera *Stapelia*, *Mesembryanthemum*, and *Diosma*, are found, and on the mountains *Protea*, *Erica*, and *Crassula*. The cultivated plants are those of Europe, with the *Musa Parodisiaca*, *Convolvulus Butatas*, the Tamarind, and *Sorghum Caffrorum*.

24. The Region of *Eucalypti* and *Epacridaceæ*. It includes extra-tropical Australia and Van Diemen's Land: temperature 52.25° to 72.5° . Vegetation is not abundant in this region; but this deficiency is compensated by the variety and peculiarity of its forms. The most abundant of the trees are the *Eucalypti*, which form three-fourths of all the woods. Next come the genera of *Proteaceæ*, *Banksia*, *Nakea*, *Dryandra*, *Grevillea*, &c.: and next to these follow *Epacridaceæ*, *Diosmaceæ*, and *Casuaraceæ*. Its cultivated plants are all European.

25. The Region of New Zealand includes the two New Zealand isles: temperate. One-half of the species are European. The vegetation is not characterised by the prevalence of large groups. Some of the genera approximate the South African flora, and some the Australian.

(The following works should be consulted on the geography of plants:—Linnaeus, *Stationes Plantarum*; Humboldt and Bonpland, *Essai sur la Géographie des Plantes*; Humboldt, *De Distributione Geographica Plantarum*; Brown, *General Remarks on the Botany of Terra Australis*; Schouw, *Grundsätze einer Allgemeinen Pflanzen-Geographie*; Meyen, *Grundriss der Pflanzen-Geographie*; Bischoff, *Lehrbuch der Botanik*; Hooker, in Murray's *Dictionary of Geography*; De Candolle, art. *Géographie des Plantes*—*Dict. des Sciences Naturelles*; Lindley, *Int. Bot.*, 2nd. ed.; Meyen, *Geography of Plants*, translated for Ray Society by Miss Johnston; Balfour, *Class-Book of Botany*; Johnston, *Physical Atlas*.)

VEGETABLE MORPHOLOGY. [METAMORPHOSIS.]

VEINS, a part of the vascular system of the higher animals. The veins return the blood which has been brought by the arteries into the capillaries to the right side of the heart. [ARTERIES; CAPILLARIES.] The veins, like the arteries, are elastic tubes, which ramify throughout the body. They are generally placed more superficially than the arteries, but some of them are deep-seated. They anastomose more frequently than the arteries.

The veins have much thinner coats than the arteries, and collapse when cut across or emptied. In most veins of tolerable size three coats may be seen, which have been named External, Middle, and Internal. The External Coat is strong and tough, but thin, and is composed of fibres of the same nature as those of areolar tissue. The Internal Coat is very like that of arteries. It consists of a membrane of fine elastic fibres, which are covered over with a layer of epithelial cells. Between these two coats is a layer of fibres, which in some places is more distinct than at others, and is then called a Middle Coat. The coats of the veins are supplied with nutrient arteries, the so-called *Vasa Vasorum*.

The veins are provided with valves, by means of which the blood is prevented from returning in the direction in which it is moving. The valves are formed of semilunar folds of the lining membrane, which are strengthened by the deposit of fibres of white and yellow areolar tissue. These flaps, or folds, are usually placed opposite each other, and are so placed as to offer no obstruction to the onward flow of the blood, but when from pressure or any other cause it is driven backwards, the reflex current will press the valves inwards until their edges meet in the middle and block the channel entirely up. In many veins these valves are absent, nor are they observed in the veins of reptiles

and fishes; and there are but few in those of birds. It was the circumstance however of the occurrence of these valves that arrested the attention of Harvey, and led him to pursue the course of the blood from one side of the heart to the other. [HEART.]

VEINS, MINERAL. [MINERAL VEINS.]

VELELLA. [ACALEPHÆ.]

VELIA. [HYDROMETRIDÆ.]

VELLA (Latinised from Velcor, the Celtic name of the Cress), a genus of plants belonging to the natural order *Cruciferae*. It has an ovate pouch, with a dilated winged leafy flat style, longer than the convex valves. The flowers are yellow, and are, as well as the pod, erect.

V. annua was found in the time of Ray on Salisbury Plain, but has not since been noticed. It has doubly pinnatifid leaves and deflexed pouches.

V. pseudocytisus, False Cytisus, or Cress-Rocket, is a native of Spain; it has yellow petals with long dark-purple claws; the larger stamens are connate by pairs; the seeds two in each cell.

VELUTINA, Lamarck's name for a genus of his family *Macrostomata*, from the rest of which however *Velutina* remarkably differs. The shell is subglobose; spire short, composed of two rapidly enlarged ventricose whorls; aperture large, subovate; peristome thin, entire, separated from the last whorl; columella twisted and thin; epidermis velvety.

Dr. J. E. Gray places the *Velutina*, with the single genus *Velutina*, between the *Truncatellidæ* and the *Paludinidæ*.

Ex. *Velutina levigata*.

Velutina levigata.

VENERICA'RDIA. [SUBMYTILACEÆ.]

VENERIDÆ, a family of Conchiferous *Mollusco*.

The genus *Venus* of Linnaeus was arranged by him in the second section (*Bivalvia: Concha*) of his *Testacea Mollusca Simplicia, oblecta Testa Calcarea*, between *Donax* and *Spondylus*.

He divided the genus into the following sections:—

* *Pubentes*.

Species:—*Dione*, *Paphia*, *marica*, *dysera*.

** *Impuberes Subcordatæ*.

Species:—*Venus verrucosus*, *casina*, *cellata*, *gallino*, *pelucia*, *flexuosa*, *erycina*, *mercenaria*, *islandica*, *chione*, *maculata*, *meretrix*, *lata*, *castrensis*, *Phryne*, *Meröe*, *defflorata*, *fimbriata*, *reticulata*, *equamosa*.

*** *Impuberes Orbiculatæ*.

Species:—*V. tigrina*, *prostrata*, *Pennisylvanica*, *incrastata*, *punctata*, *croleta*, *borealis*, *pectinata*, *scripta*, *edentula*.

**** *Impuberes Ovales*, supra rimam subangulatas.

Species:—*V. literata*, *rotundata*, *decussata*, and *virginica*.

Such is the arrangement of Linnaeus in his last edition of the 'Systema Naturæ,' and he characterises the hinge of the genus as consisting of three teeth, all approximate, the lateral teeth diverging at the apex.

The *Cardiaceæ* of Cuvier consist of the genera *Cardium* (with the sub-genus *Hemicardium*), *Donax*, *Cyclas* (with the sub-genera *Cyrena*, *Cyprina*, and *Galathea*), *Corbis*, *Tellina*, *Loripes*, *Lucina*, *Ungulina*, *Venus*, *Corbula*, and *Maetra* (including the true *Maetra* and the *Lavigons*).

The genus *Venus* he divides into the true *Veneres*, *Astarte* or *Crassina*, *Cytherca*, *Capsa*, and *Petricola*; and he defines this great genus *Venus* as comprising a multitude of shells whose common character is to have the teeth and laminae of the hinge approximated under the umbo in a single group. They are, he remarks, in general more flattened and more elongated parallelly to the hinge than the *Cardia*. Their ribs, when they have any, are nearly always parallel to the borders, which is the opposite of the *Cardia*. The ligament often leaves behind the umbones an elliptical impression named by modern zoologists the Corset; and there is nearly always in front of the umbones an oval impression designated as the Lunule.

The animal has always two tubes susceptible of more or less projection, but sometimes united to each other, and a compressed foot which serves for creeping.

Dr. J. E. Gray places the *Veneridæ* as the first family of his order *Phyllopora*, with the following genera:—*Artemis*, *Cytherca*, *Meröe*, *Gratelupia*, *Trigona*, *Chione*, *Circe*, *Dosina*, *Mercenorio*, *Anomolocardio*, *Cyprerio*, *Venus*, *Tapes*, *Venerupis*, and *Clementia*.

The *Veneridæ* are immediately followed in Dr. Gray's arrangement by the *Cyrenidæ*, which comprise the following genera:—*Cyrena*, *Geloina*, *Veloria*, *Cyclas*, and *Paidium*.

The *Cardiacæ* immediately follow. Woodward, in his 'Manual,' places the *Veneridæ* between the *Cyprinidæ* and *Maetridæ*, and includes

in it the following genera:—*Venus*, *Cytherea*, *Meroe*, *Trigona*, *Artemis*, *Lucinopsis*, *Tapes*, *Venerupis*, *Petricola*, and *Glaucomya*.

Our limits will only permit the illustration of this family by the notice of a few genera.

Cyrena.—M. Deshayes, in his last edition of the 'Animaux sans Vertèbres,' remarks of the genus *Cyrena* that there exists a passage between the two genera, but a point is arrived at where the species become very distinct from *Cyclas* by reason of their thickness and having one tooth more in the hinge. The animal of the *Cyrena* which M. Deshayes had seen did not differ essentially from that of *Cyclas*, and approached nearly to that of *Venus*. It has the two lobes of the mantle united in their posterior third, and prolonged on that side by two siphons, which are separated to the base. They are furnished with a small retractor muscle, which leaves a particular impression in the shell.

The number of species of *Cyrena* is about 25. They are mostly found in tropical seas. There are about 75 fossil species found from the Wealden upwards.

C. fuscata is brownish-green, with numerous transverse subimbricate furrows; violet within and at the umbones; the lateral teeth very much elongated transversely and denticulated. It is a native of the Chinese rivers and those of the Levant.

Cyrena fuscata.

Megadasma.—Shell equivalve, subtrigonal, covered with a greenish epidermis. Hinge-teeth furrowed; two in the right valves connivent at their base; three in the other valve, the intermediate one advanced and separated. Lateral teeth distant. Ligament external, short, projecting, convex. Nymphæ prominent. (Lam.) Animal with a thick subtrigonal body; the mantle large, simple, open below and in front, closed posteriorly, and prolonged on that side into two equal tubes separated at the base; two unequal branchiæ, the upper one folded double; four triangular buccal appendages; mouth large; foot large, oblong, compressed, subangular anteriorly. (Deshayes.)

M. radiatum (*Galathea radiata*, Lam.; *Potamophila radiata*, Sow.). Under the epidermis milk-white, marked with violet towards its base, and ornamented with violet rays, generally from two to four in number. It is found in the rivers of Ceylon and of India.

Cyprina.—Shell equivalve, inequilateral, obliquely cordate; umbones obliquely curved; hinge with three unequal teeth, approximated at the base, subdivaricate above; lateral tooth distant from the hinge, on the anterior side, sometimes obsolete; nymphal callosities large, arched, terminated near the umbones with an ovate lunule. Ligament external, often partly immersed under the umbones.

The species are generally found in sandy mud.

C. Islandica has the shell cordate, transversely striated, covered with an epidermis; the anterior side subangulate. It is a native of the Northern Ocean, at the mouths of rivers.

Cyprina Islandica.

Cyprina occurs below the Chalk. Ninety fossil species have been described.

Cytherea.—Shell equivalve, inequilateral, suborbicular, trigonal, or transverse. Four cardinal teeth in the right valve, of which three are divergent, approximated at their base, and one is entirely isolated, situated under the lunule. Three divergent cardinal teeth in the other valve, and a fosset at a little distance parallel to the border. No lateral teeth. (Lam.)

Lamarck states that in *Cytherea* there are constantly four teeth in the hinge. The fourth tooth is very oblique, and always set in that part of the border which comprises the lunule. This tooth is in fact constant in a considerable number of species; but in more than twelve, living as well as fossil, which M. Deshayes had carefully examined, he saw this tooth diminish by little and little, and become so rudimentary that, it having sometimes escaped Lamarck's notice, the latter comprised many of this species in his genus *Venus*, and placed the others among the *Cythereæ*. If, says M. Deshayes in continuation, these observations are just—and it will be very easy to verify them in a large collection of living and fossil species of the two genera—one may ask where the line is to be drawn, and what reasonable ground exists for their separation?

The number of species noted in the Tables of M. Deshayes is 85 recent and 59 fossil (tertiary). Of these *C. erycina*, *C. chione*, *C. nitidula*, *C. citrina*, *C. exoleta*, *C. concentrica*, *C. lincla*, *C. rufescens*, *C. multilamella*, and *C. venetiana* are stated as occurring both recent and fossil (tertiary).

In the last edition of Lamarck the number of recent species recorded is 78; and the number of fossil species is 9. Mr. Lea, in his 'Contributions to Geology,' adds 6 species from the Claiborne Beds (tertiary of Alabama).

One of the most remarkable species is *C. dione* (*Venus dione*, Linn.). This remarkable shell, of which there are many varieties, is obliquely cordate in shape, of a rosy, rosy-purpurescent, purpurescent, or viuous colour, transversely furrowed with elevated lamellæ; the posterior borders of the shell are beset with spines, very long and distant in some varieties, and short and close-set in others.

It is a native of the seas of America.

Venus (Cytherea) dione.

C. meretrix has the shell trigonal, smooth, white; the umbones spotted; posterior surfaces olivaceous cerulescent, anterior side angulate.

Venus (Cytherea) meretrix.

There is a variety zoned with chestnut, with the sides and margins white.

Cytherea occurs fossil below the Chalk.

Venus.—Shell equivalve, inequilateral, transverse, or suborbicular. Three cardinal teeth, approximated, in each valve; the lateral ones diverging at the umbo. External ligament covering the external anterior fissure.

The number of species recorded by M. Deshayes in his Tables is 101 recent and 43 fossil (tertiary). Of these *V. verrucosa*, *V. pilicata*, *V. gallina*, *V. decussata*, *V. radiata*, *V. Brongniarti*, *V. dysera*, *V. geographica*, and *V. paphia* are noted as recent and fossil (tertiary).

In the last edition of Lamarck the number of recent species recorded is 96, and the number of fossil 13. Woodward gives 176 recent and 160 fossil species.

Although species of *Venus* are to be found in most seas, they are most numerous in those of warm countries, and generally at a moderate distance from the shore.

V. cancellata has the shell cordate, longitudinally sulcate, girt with elevated remote transverse belts; white, spotted with bay or brown; lunule cordate.

It is a native of the seas of America.

M. Deshayes thinks it evident that Lamarck's species is identical with *Venus dysera*, Chemn., that it ought to be suppressed, and that a new name should be given to Chemnitz's variety, which is very distinct. The reader will find the synonyms collected, and the confusion learnedly unravelled, in the last edition of the 'Animaux sans Vertèbres.'

Venus cancellata.

V. (Pullostera) textile. Shell ovate oblong, very smooth, pale-yellow, ornamented with angulate-flexuous, purplish, or cerulescent lines.

It is a native of the Malabar coast.

Venus (Pullostera) textile.

We subjoin a representation of *Venus (Pullostera? Venerupis?) vulgaris*. [LITHOPHAGIDÆ.]

Venus (Pullostera Venerupis) vulgaris.

Venus occurs fossil below the chalk.

VENERUPIS, or VENERURUPIS. [LITHOPHAGIDÆ.]

VENICE WHITE. [BARYTES.]

VENOM-FANGS. [OPHIDIA; VIPERIDÆ.]

VENTILAGO, a genus of Plants consisting of only a single species, belonging to the natural order *Rhamnaceæ*. The calyx is 5-parted; the corolla 5-petalled; stamens 5; germ 2-celled, lid in the creuclated flat disc; style 2-cleft. Samara half superior, globose, long-winged, 1-seeded; embryo erect with perisperm. The species *V. maderas patana* is common in different parts of India, from the peninsula to the north-western provinces; it is also found in the Indian islands, as it is figured and described (Rumph., 'Herb. Amb.', 5, t. 2) by the name of *Funis riminalis*. It forms a large climbing shrub with stiff branches; is often dioecious, with flowers having an offensive smell, not unlike that of *Sterculia fetida*.

VENTRICLE. [HEART.]

VENTRICULITES, a genus of Spongioid Zoophyta, proposed by Dr. Mantell for species found in the Cretaceous System, whose porous tissue is penetrated by distinct often large foramina, arranged with more or less of regularity. *V. radiatus* (Mantell, 'Geol. of Sussex,' pl. 10) and *V. Bennettii* (pl. 15 of the same work) are examples frequently found in chalk and the flint nodules imbedded in it.

VENUS. [VENERIDÆ.]

VENUS'S FLY-TRAP. [DIONEÆ.]

VERATRUM, a genus of Plants belonging to the natural order *Melanthaceæ*. The name *Veratrum* occurs both in Pliny and Lucretius, but whether these were the same plants as the modern genus it is now impossible to say. It is also supposed to be the 'Ελλεβορος λευκός of Dioscorides; and the name White Hellebore, which is given to one of the species, seems to confirm this view. The genus is characterised as follows:—Perianth composed of six permanent, sessile, equal parts, to which are attached 6 stamens; styles 3, permanent, with simple spreading stigmas; capsules 3, bursting at their inner margins, by which they are originally united; seeds numerous, compressed, imbricated, winged at each end; several of the flowers have only the rudiment of an ovary.

V. album, Common White Hellebore, has a thrice compound panicle with ascending elliptical pieces of the perianth; the bracts of the branches oblong, partial, as long as the downy peduncle. It is a native of moist alpine meadows in the southern, central, and northern parts of Europe, but is not a native of Britain. In company with the *Gentiana lutea* it is one of the most prominent features in the rich pastures of the Alps of Switzerland and Savoy. The stem, which is from two to four or five feet in height, proceeds from a black, fleshy, wrinkled fusiform rhizoma, or rootstock, which is beset with a number of small radicles. [VERATRIA, in ARTS AND SC. DIV.]

V. viride, Green-Flowered Veratrum, has panicle racemes, with the bracts of the branches oblong-lanceolate, partial, longer than the downy petiole. This is a North American species, and is found in swamps and bogs from Canada to the Carolinas. It is found, according to Dr. Bigelow, in the swamps around Boston, where it is called Poke-Root, or Swamp Hellebore.

V. nigrum, Dark-Flowered Veratrum, has dense cylindrical panicle racemes with the bracts of the branches linear-lanceolate, and very long, pieces of the perianth obovate, widely spreading, and at length reflexed. It is a native of dry mountainous situations in Siberia, Hungary, Austria, and Greece. It will grow freely in gardens in Britain, especially in a light soil.

V. Sabadilla, Caustic Veratrum, at one time supposed to yield the

Cebadilla of commerce, and from which the poisonous alkaloid Veratrine of the Pharmacopœia is directed to be prepared, has broad ovate plantaginaceous leaves, dark purplish-black flowers, and capsules situated on only one-half of the circumference of the stem. This plant appears to be a native of the West Indies and Mexico, whence also the true Cebadilla plant comes to this country. The true Cebadilla plant has been stated by David Dou to be the *Helonias officinalis*, and more recently, by Lindley, *Asagrea officinalis*. Previous to this however Schiede, who travelled in Mexico, sent home specimens of plants of Cebadilla, agreeing more with *Veratrum* than any other genus, and which Schlechtendal named *Veratrum officinale*. Dr. Christison, after an examination of the fragments of racemes, which occur in commerce as Cebadilla, is inclined to think that Schiede's plant supplies the greatest quantity to the market, although it is not improbable that this and several allied species are frequently substituted for one another, as the quantity of Veratrine they contain is much the same. [CEBADILLA.]

VERBASCUM, a genus of Plants belonging to the natural order *Scrophulariaceæ*. It derives its name from 'barbasicum,' which was applied to some of the species on account of the bearded filaments; hence also the Italian name 'barbasso.' It has a 5-parted calyx; rotate funnel-shaped corolla; 5 stamens, all bearing anthers, which are only occasionally not all lunate in the same flower; a 2-valved capsule with seeds attached to the central placenta. There are about 70 species: they have strong erect stems, with broad decurrent leaves, and yellow, white, or purple flowers, disposed in dense or loose racemes or spikes.

V. Thapsus, Great Mullein, has crenated decurrent oblongo-lanceolate tomentose leaves; dense racemose spikes; pedicels of the flowers shorter than the calyx; the segments of the calyx lanceolate, acute, and tomentose above, and equal in length to the fruit; the corolla with the anther nearly equal. This plant is a native of waste sterile places, especially of chalky and gravelly soils, throughout Europe. It is also found in Siberia, Taurus, and Caucasus, and in Nepal and Kumaon. The leaves are remarkable for their woolly character, from which the English name Mullein seems to have been applied to the whole genus. Mullein (French, Molène) is said to be a corruption of Woollen, and in German the plants are called Wollkräuter. In different districts in England this plant has very various names. In the northern counties it is called Hag-Taper, from some supposed efficacy in sorcery: in many places this has been corrupted into Hig-Taper and High-Taper. Torches, Bullock's Lung-Wort, Hare's Beard, Ladies' Fox-Glove, Murrain-Grass, Shepherd's-Club, &c., are other names. The specific name *Thapsus*, has been given to it on account of its growing in great abundance at Thapsos in Africa. It is also abundant in Greece, and appears to have been the *Φλόμος λευκός ἄρρηγν* of Dioscorides. This plant was formerly much used in medicine, and was considered to possess emollient and narcotic properties, and on this account it still occupies a place in the Dublin Pharmacopœia. The French call this plant Bouillon Blanc, and use an infusion of the flowers as a remedy in coughs. When dried in the sun the flowers are said to give out a fatty matter, which in Alsace is used as an application to hemorrhoids.

V. Blattaria, Moth Mullein, has glabrous leaves, the lower ones obovate-oblong, attenuated at the base, and somewhat sinuated; those of the stem oblong, acute, crenated, sessile; the racemes terminal, elongated; the pedicels solitary, twice as long as the bracts. It is a native of the middle and south of Europe, some parts of Asia, and North America. It is not a common plant in Great Britain, although in some places it is abundant. It is called *Blattaria*, because it is said to drive away the *Blatta*, or Cockroach.

V. pulcherrimum, Yellow Hoary Mullein, has ovato-oblong subserrated leaves, pulverulent-tomentose on both sides; racemes paniced; pedicels equal in length to the calyces; stem rounded. This plant is a native of Dauphiny and of Great Britain, especially in the counties of Norfolk and Suffolk.

V. nigrum, Dark Mullein, has oblongo-cordate petiolate crenated leaves, nearly smooth above, but clothed with fine tomentum beneath; racemes elongated; pedicels twice as long as the calyx. It is a native throughout Europe and in Siberia, and is common on banks and waysides in gravelly and chalky soils in England.

V. Lychnis, White Mullein, has oblong wedge-shaped leaves, nearly glabrous above, but clothed with tomentum below; racemes paniced; pedicels twice as long as the calyx. It is found amongst rubbish and in waste places throughout Europe, in the north of Asia, and in North America, and is not uncommon in Great Britain. The powdery tomentum is used as tinder, and for making wicks for lamps, and hence its specific name from *λύχνος*, a lamp. The other British species are *V. thapsiforme*, *V. soccozum*, and *V. virgatum*.

VERBENA, a genus of Plants, the type of the natural order *Verbenaceæ*. Most of the species of this genus are weeds, and are generally inhabitants of Europe and North America. The genus is known by a tubular calyx with 5 teeth, one of them generally shorter than the rest; a tubular corolla with the limb rather unequal, 5-cleft; the stamens included, and sometimes only 2; the seeds 2 or 4, inclosed in a thin evanescent pericarp.

V. officinalis, Common Vervain, has 4 stamens with an erect somewhat hispid stem; the leaves lanceolate, inciso-serrate, or trifid, with the segments cut rough; the spikes filiform, somewhat paniced, and

the flowers rather remote. This plant is common in England. It is not found in Ireland. It is an inhabitant also of Australia. This is the *ἱερὰ ῥόδα*, 'holy herb,' of Dioscorides, who ascribed great powers to it, especially in incautions. In most countries where it grows it seems to have been invested with extraordinary powers. It at one time entered into the composition of various charms and love-philters, and has even now a popular reputation for predisposing persons favourably towards those who administer a dose to them. The ancient Druids revered it next to the mistletoe, and gathered it with religious ceremonies.

V. Aubletia, Rose-Coloured Vervain, is a native of North America, in Georgia and the Carolinas, and was first brought to Europe in 1774. It is known by its fine pink or crimson flowers.

V. triphylla, Lemon-Scented Vervain, has paniced spikes, with minutely distantly-toothed leaves, three in a whorl; stem shrubby. This plant is a native of Chili. It is used on the continent for making an infusion, which, when cold, is administered as a cooling drink in fevers, slight catarrhs, &c.

VERBENACEÆ, *Verbens*, a natural order of Exogenous Plants. The species are trees or shrubs, sometimes only herbaceous plants, with generally opposite, simple, or compound leaves without stipules. The flowers are in opposite corymbs or spiked alternately, sometimes in dense heads, and very seldom axillary or solitary. The calyx is tubular, persistent, inferior; the corolla is hypogynous, monopetalous, tubular, deciduous, generally with an irregular limb; the stamens 4, didynamous, seldom equal, occasionally 2; ovary 2-4-celled; ovules erect or pendulous, solitary or twin; style 1; stigma bifid or undivided; fruit nucamentaceous, sometimes berried, composed of two or four nucules in a state of adhesion; seeds erect or pendulous, albumen none, or in very small quantity; embryo always erect. (Lindley.)

The great difference between these plants and those of *Lamiaceæ* or *Labiata* consists in their concreto carpels, terminal style, and the absence of oil-glands from their leaves.

Verbena mutabilis.

1, cutting with flowers; 2, corolla opened with didynamous stamens; 3, calyx opened with nucamentose fruit; 4, section of single fruit; 5, single carpel.

The plants of this order are rare in Europe, in the north of Asia, and in the north of America; they are common in the tropics of both hemispheres, and in the temperate districts of South America.

The plants belonging to this order have no very active properties; those attributed to the Vervain [VERBENA] appear to have been imaginary. The *Lantana pseudothee* is said, by Geoffroy St. Hilaire, to be used in Brazil as a substitute for tea, and is vulgarly called Capitaô do Matto, or Cha de Pedreste. [LANTANA.] The Teak-Tree [TECTONA],

also the Brazilian Tea-Tree [*STACHYTARPIA*], and the Chaste-Tree [*VITEX*], belong to this order.

VERD-ANTIQUE. [MARBLE.]

VERDETER. [COPPER.]

VERMES. Ancient naturalists designated by this name all lower animals resembling in form the Earth-Worm. Linnæus adopted it as the title of a class, including all animals which he could not arrange under the *Vertebrata* and *Insecta*.

VERMETUS. [TUBULIBRANCHIATA.]

VERMICULITE, a Mineral, described by Dr. Thomson as composed of micaceous-looking plates cemented together by a whitish matter. Lustre soapy. Feel greasy. Sectile. Hardness 1. Specific gravity 2.5252. When heated nearly to redness it projects out with a vermicular motion, as if it were a mass of small worms: hence the name. By ignition it becomes of a silvery aspect, with a shade of red or yellow. Infusible per se before the blow-pipe. With carbonate of soda in the reducing flame gives a greenish, in the oxidising flame an anæthyist coloured glass. Dr. Thomson's analysis gave:—

Silica	49.080
Magnesia	16.964
Peroxide of Iron	16.120
Alumina	7.280
Water	10.276
Manganese	a trace

— 99.72.

VERMILIA, a genus of *Serpulidæ* [TUBICOLÆ], composed of species of *Serpula* which are attached by the whole length of the shell, such as *Serpula* (*Vermilia*) *triquetra*, the shell of which is repent and flexuous, with a simple dorsal carination: there is a variety with a red line on each side of the carination. It is a native of European and Mediterranean seas, on stones, shells, and other submerged marine bodies.

Vermilia triquetra.

VERMILIO. [LEPTIDES.]

VERMILION. [MERCURY.]

VERNAL GRASS, SWEET. [ANTHOXANTHUM.]

VERNATION. [LEAF.]

VERNICIA, a name applied by Loureiro to a Plant of Cochinchina, which is well known as yielding an oil, and which belongs to the same genus as another plant, also yielding an oil, in China and Japan. By Thunberg the latter plant was called *Dryandra*, but that name being appropriated to a genus of *Proteaceæ*, these oil-trees are now referred to the genus *Elæococca* of Commerson. This genus belongs to the natural order *Euphorbiaceæ*. *E. verrucosa* the *Dryandra oleifera* of Lamarck, and the *D. cordata* of Thunberg, is a native of Japan, where, he states, it is called Ahassin: the oil expressed from its seeds is used both as an article of diet and for affording light. The Chinese are said to call the oil Mouyeou, and the fruit from which it is obtained Mouyou. The tree cultivated in Bourbon is there called Arbre d'huile, where an oil is likewise obtained by submitting the almonds of the seeds to pressure. *E. montana*, the *Vernicia montana* of Loureiro, is a native of China and Cochin-China: it yields a clear yellowish fatty oil, which is employed to protect wood from the influence of air and water. It is sometimes mixed with the real varnish of these countries, which it makes more liquid, but less valuable as a resin.

VERNONIA, named after W. Vernon, a genus of Plants belonging to the natural order *Compositæ*. *Vernonia* (*Serratula*, Roxb.) *anthelmintica* is a pretty, large, erect, annual species, common on dry uncultivated ground and rubbish in different parts of India, flowering during the cold season. The dark-coloured seeds are extremely bitter, and considered powerfully anthelmintic. They are also employed as an ingredient in compounds prescribed in snake-bites.

VERNONIA-CEÆ, a tribe of Plants belonging to the natural order *Compositæ*. They are distinguished from *Lactucæ* by their corolla, which is not ligulate, and from every other tribe by their style, which is the same as that possessed by *Lactucæ*. There are

several genera of plants belonging to this tribe, which are chiefly inhabitants of America: there are a few in Asia and Africa, but none in Europe.

VERONICA, a genus of Plants belonging to the natural order *Scrophulariaceæ*. The species consist of herbs, undershrubs, or shrubs, with opposite, alternate, or verticillate leaves. The flowers are of a blue, white, or red colour, and are arranged in spikes or racemes; the calyx is campanulate or compressed, 4-5-parted; the corolla rotate, with a very short tube, a 4-parted spreading limb; all the segments entire, the upper one the broadest; the stamens are 2, situated at the sides of the upper segment of the corolla, diverging; anthers 2-celled; stigmas hardly thickened. The fruit a capsule, with a septum in the middle or bipartite. The species of this genus are exceedingly numerous; they are distributed over all parts of the world, and are especially abundant in temperate climates. The flora of Great Britain contains about 20 species.

V. spicata, Spiked Speedwell, has its flowers on a spiked raceme; the leaves crenated, the radicle ones ovate or obovate, and running into the petioles; the cauline leaves are lanceolate or oblongo-lanceolate, sessile, toothed, and entire at the top; the whole plant downy, canescent, and rather clammy. It is a native of Germany, France, and Switzerland, and is found in England, in some parts of the county of Suffolk.

V. officinalis, Common Speedwell, has spicate flowers, with leaves broadly ovate, serrated, and rough with pubescence; stem very downy, procumbent; the capsule obovate, deeply notched; the bracts longer than the pedicles of the flowers. It is a native of Europe and North America, in woods and on dry sandy banks, and is plentiful in Great Britain. It has pale blue-coloured corollas, with veins of a deeper blue. Paullix, an old Danish botanist, endeavoured to prove that this plant was identical with the Tea-Plant of China, and it was once extensively used as a substitute for tea.

V. Beccabunga, Brooklime, is a glabrous shining plant, with procumbent stems, and elliptic oval or oblong leaves, seated on short petioles, serrated or entire. It is a native of every country in Europe, and is also found in North America and Nepal, and is abundant in Great Britain.

V. montana, Mountain Speedwell, has lax few-flowered racemes, with ovato-cordate serrated petiolate leaves; a stem hairy all round; and an orbicular 2-lobed membranous capsule much larger than the calyx. It is a native of Europe, but is not very common in Great Britain.

V. Chamædrys, Germander Speedwell, has the whole plant hairy; the leaves deeply and unequally serrated; the racemes elongated and many-flowered; the capsule obovate and shorter than the calyx. It is common throughout Europe.

V. Teucrium, Germander-Leaved Speedwell, is a downy plant, with the lower leaves ovate oblong, half-clasping the stem, obtuse, and coarsely serrated, the upper ones sessile, narrower, and serrated; the racemes axillary, opposite, on long peduncles, and the stems ascending or prostrate. It is a native of Italy, Switzerland, and Germany, in clayey soils.

The other British species are *V. scutellata*, *V. Anagallis*, *V. saxatilis*, *V. alpina*, *V. serpyllifolia*, *V. arvensis*, *V. verna*, *V. triphyllus*, *V. agrestis*, *V. polita*, *V. Buxbaumii*, and *V. hederifolia*.

VERRUCA. [CIRRHEDIA.]

VERRUCA'RIA, a genus of Plants belonging to the natural order of Lichens. The species of this genus are found on rocks and flints and the bark of trees, and are abundant inhabitants of Great Britain.

VERTEBRA is the name given to each of the separate bones of which the spinal column of the skeleton of the *Mammalia* is composed. [SKELETON.] Although in technical anatomy the term is thus restricted, it has recently received a much more extended signification. Professor Owen defines a vertebra as "one of those segments of the endo-skeleton which constitute the axis of the body and the protecting canals of the nervous and vascular trunk; such a segment may also support diverging appendages." According to this definition, the vertebra becomes the type or plan on which all the bones of the skeleton of vertebrate animals are constructed. It is not only a portion of the spinal column, but the elementary form to which all the parts of the skeleton may be reduced. The bones of the head, of the thorax, the pelvis, and the limbs, however complicated, are reducible to the plan of the typical vertebra. In the history of the development of this interesting branch of anatomical inquiry a variety of opinions have been expressed, as to what may be regarded as the true elements of a typical vertebra, since in no instance do we find all the parts of the vertebra developed in exactly the same manner.

The diagram in next page exhibits a typical vertebra, according to the plan of Professor Owen.

This plan does not include the parts which constitute the diverging appendages. Of this plan Professor Owen says, "The names printed in Roman type signify those parts which, being usually developed from distinct and independent centres, I have termed 'autogenous' elements. The italics denote the parts more properly called processes, which shoot out as continuations from some of the preceding elements, and are termed 'exogenous'; e.g., the diapophyses, or upper transverse processes, and the zygapophyses, or the 'oblique' or 'articular processes' of human anatomy."

Ideal Typical Vertebra.

The autogenous processes generally circumscribe holes about the centrum, which in the chain of vertebræ form canals. The most constant and extensive canal is that formed by the neurapophyses for the lodgment of the trunk of the nervous system, and marked *n* in the diagram. The second canal is formed by the hæmapophyses, and is below the centrum, and embraces the central circulating organ (*h*), the heart, and the large trunks of the vascular system. At the sides of the centrum, most commonly seen in the cervical region, rise two other canals, formed by the three lateral elements of the vertebra, and these often embrace an artery and a nerve. Thus a typical or perfect vertebra, with all its elements, presents four canals or perforations about a common centre; such a vertebra is seen in the thorax of man, and most of the higher forms of vertebrate animals, as in the neck of many birds. In the tails of most reptiles and *Mammalia* the hæmapophyses are articulated or anchored to the under part of the centrum, space being needed there only for the caudal artery and vein. But where the heart is to be lodged an expansion of the hæmal arch takes place, analogous to that which occurs in the neural arches when the nervous trunk assumes the form of a brain.

In the same manner that the parts of the thorax, spinal column, and skull may be traced to the elements above referred to, the parts of the two pairs of locomotive organs with which all vertebrate animals are endowed may be traced to a common plan in the diverging appendages. These parts of all others are most subject to change,—now developed to an enormous extent, and again almost entirely disappearing, according to the necessity of adapting the animal to its special habits. With the exception of the posterior and anterior extremities, these organs are developed only to a limited degree. It is through the study of these appendages that the pectoral fins are seen to be the homologues of the anterior extremities in the Reptiles, of the wings in the Birds, of the fore legs in the majority of the *Mammalia*, the flippers of Seals and Whales, and of the arms in Man. In like manner the abdominal fins of Fishes are the homologues of the legs in Birds, and of the posterior extremities of the Reptiles and *Mammalia*, and the legs in Man. These homologues include not only the totality of these organs, but the individual parts, and the scapula, clavicle, coracoid process, humerus, radius, ulna, carpal and metacarpal bones, and phalanges, in the higher *Mammalia* and Man have their homologues in the lower form of vertebrate animals. So with the pelvic arch, with its ilium, ischium, pubis, femur, fibula, tibia, tarsal and metatarsal bones, and phalanges.

We have not space here to enter into the details of the application of this general plan to the structure of the skeleton of the various forms of vertebrate animals, but this has been done in a most masterly manner by Professor Owen, in his 'Report on the Homologies of the Vertebrate Skeleton,' published in the 'Transactions of the British Association' for 1846, and also subsequently in an independent volume devoted to the same subject. This department of anatomical inquiry is no longer a matter of ingenious hypothesis and verbal speculation, but has been placed by this inquirer, through the unerring principles of comparative anatomy and development, upon the firmest basis, and may be regarded as an essential part of scientific truth.

VERTEBRATA. [MAMMALIA.]

VERTICILLUS. [INFLORESCENCE.]

VERTIGO, a genus of Gasteropodous *Mollusca*. The shell is cylindrically fusiform, sinistral, hyaline; the aperture margined, sinuous, and denticulate on the inner edge; the peristome somewhat reflected.

Vertigo pusilla. Great Britain.

Pupa; but the shells are sinistral, or left-handed, to use the collector's term, and of a glassy transparency. [HELICIDÆ.]

VERUNA. [GRAFIDÆ.]

VERVAIN. [VERBENÆ.]

VESPERTILIO. [CHEIROPTERA.]

VESPERTILIONIDÆ. [CHEIROPTERA.]

VESPIDÆ, a family of Insects belonging to the order *Hymenoptera*. It comprises the species of the genus *Vespa* of Linnaeus, of which the common Wasp and the Hornet are familiar examples. They were formed into a family by Latreille, under the name of *Diploptera*, afterwards changed into *Diplopteryga* by Kirby. They form the third and last division of the first sub-section (*Prædones*), of the second section (*Aculeata*) of *Hymenoptera*, in Westwood's revision of Latreille's arrangement. When at rest they fold their wings throughout their entire length, whence their distinctive appellation. The wings of all the insects of the family have a similar neurotation, their eyes are lunate, and there are glands at the extremity of the labrum. The fore wings have one marginal and three perfect submarginal cells, with an incomplete terminal submarginal cell.

Whilst some of these characters are so peculiarly distinctive of the *Diplopteryga* that they are not to be seen in any other insects of the order, they, strange to say, do not at all indicate a community of habits. Among the Wasps are insects of the most dissimilar habits; some solitary, others living in societies, some phytophagous, others carnivorous. Such as are social rival the bees in the complicated instincts which regulate their societies. At first sight these great differences of manners would seem to point to a classification superior to that founded on such unimportant characters as the folding of the wings, &c. But when we find on further inquiry that the latter apparently insignificant distinctions correspond to essential modifications of structure common to all the insects of the family, we are led to conclude that among the Wasps, structure, and not economy, is the real source of essential character. Some authors, laying greater stress on habit than on structure, have been inclined to separate far apart the Social from the Solitary Wasps; but the utmost to which a separation can be admitted is that arrangement adopted by Mr. Westwood, namely, the division of the *Diplopteryga* into two families, the *Eumenidæ* and the *Vespidæ*.

Besides the characters already mentioned, the Wasps are distinguished by the form of the antennæ, which are usually angled and somewhat clavate at their extremities. Their tongues are trifid and laciniated at the tips; the palpi are short and filiform; the maxillæ long and compressed; their eyes are notched; the thorax is entire. The bodies of the Wasps are usually black, with yellow markings, the males differing from the females in having the clypeus not marked with yellow spots. They are naked, or but slightly hairy. The abdomen is often pedunculated, and the females and neuters are provided with a powerful sting. Their legs are unprovided with apparatus for the collection of pollen.

The Solitary Wasps, each species of which comprises males and females only, constitute the family *Eumenidæ*. The genera *Eumenes* and *Odynerus* belong to it. Their peculiarities of organisation are adaptations to their peculiarities of habit. Thus the maudilins form a kind of rostrum, resembling that of the *Fossoræ*, for the purpose of seizing and carrying off the insects on which they prey. The antennæ are composed of 12 or 13 distinct joints, according to the sex, and are pointed. The labrum is divided into four pilose setæ, with glands at their extremities; the lateral ones narrow and pointed, the intermediate longer. The clypeus is oval or heart-shaped, and anteriorly more or less truncate. The basal segment of the abdomen in the typical species is elongated into a peduncle. Their larvæ are fleshy grubs, with tubercles serving instead of feet.

The habits of the Solitary Wasps are interesting. Réaumur informs us that the *Odynerus murarius* (*Vespa muraria*) of Linnaeus makes a hole several inches deep in the sand, or in the sides of walls, constructing a tube of earthy paste, at first straight, and then curved at its entrance. In this burrow it constructs its cells, and deposits in the cavity of the interior cell from 8 to 12 little green caterpillars, arranging them spirally in layers above each other. In the midst of these it deposits its eggs, then closes the mouth of the hole with the materials of the tube, which it had used as a sort of scaffold. The larvæ when hatched feed upon the caterpillars. Mr. Westwood states that the *Odynerus Antilope* lines its cells with mud, of which it carries small round pellets into its burrow under its breast. Bouché observes that *Odynerus Parietum* stores up flies and other perfect insects, along with caterpillars, for the food of its young. In the 'Gardener's Magazine' for 1837 a most remarkable instinct, displayed by a species of *Odynerus*, is related by Mr. Westwood. The insect he describes stores in its nest the leaf-rolling larva of a *Tortrix*, which it obtains by introducing its sting into the rolls of leaves, and then running to the end of the roll to catch the larva, which it finds endeavouring to make its escape from its unknown enemy. According to Geoffroy, the *Eumenes coarctata* constructs upon stems of heaths and other plants a spherical nest of fine earth, which it fills with honey, and there deposits an egg. In the first volume of the new series of the 'Magazine of Natural History,' Mr. Shuckard gives an interesting history of a new British *Odynerus*, *O. levipes*, which builds its nest in excavations made in the

pith of dead bramble-sticks. In this case there was no appearance of any food having been laid up with the grub.

The genus *Cerumius* is an exception to its family, since its upper wings are not folded longitudinally, and are furnished with only two submarginal cells. It differs also in some other characters. In its habits it resembles the *Odyneri*. The species inhabit Europe and South Africa. The genus *Masaris*, constituting Latreille's family of *Masariidæ*, is also anomalous in some of its characters, but agrees with *Eumenes* in the manner of folding its wings.

The Social Wasps constitute the restricted family of the *Vespidæ* of Westwood, the *Polistidæ* of Saint Fargeau. They live in numerous societies, consisting of males, females, and neuters, which are temporary, being dissolved at the approach of winter. The mandibles of the *Vespidæ* proper are not longer than broad, and are broadly and obliquely truncated at their extremities. The labrum is short and but slightly elongated, and the clypeus is nearly square. They are voracious insects, preying upon others, and on meat, honey, fruit, &c. The winged insects prepare the food in their stomachs for their young, which they feed daily. The males are drones, and do not work, leaving all labour to the females and neuters. The larvæ are fleshy grubs, destitute of feet, but furnished with lateral tubercles. Some of the species, as the Hornet (*Vespa crabro*), are of considerable size. Such as belong to the genus *Vespa* build a covering to their nests. The nests of *Polistes* have the cells undefended. The nests are constructed of a papyraceous substance made from wood or the bark of trees, and those of some species include an immense number of cells of an hexagonal form, arranged in tiers with their mouths downwards; sometimes as many as 16,000. A Brazilian species makes honey. A Demerara wasp suspends its nest by a ring from the uppermost branches of trees, so as to be out of the reach of monkeys. In the collection of the Zoological Society is a wasp's nest from Ceylon, built inside a great palm-leaf, and not less than 6 feet in length. In the British Museum may be seen some curious nests of exotic species. The hornet constructs its nest of a coarser substance than that used by the common wasp, and builds it in the trunks of trees and in old walls.

Of the indigenous species, the *Vespa vulgaris* is the most common. It is a ground-wasp, as is also the *V. rufa*, a rarer species, making smaller nests and associated in less populous societies. Of Tree-Wasps we have *V. holsatica* of Linnaeus, which is the *V. Anglica* of Leach, and the *V. Britannica* of the last-named author.

Wasps live in societies, composed of females, males, and neuters, or workers, which are essentially females, but have the reproductive organs undeveloped or passive. The females are usually largest, but of them there are two sizes—one very much larger than the neuters, and laying eggs which produce two sexes, while the other is about the same size, and lays only male eggs. The larger kind are produced later than the workers, and come forth to be queens and to found new colonies in the following spring. Destined to become the monarch of a populous state, the queen-mother is at first an outcast and alone. Industry effects her greatness. With instinctive ambition, ere her subjects are born, she lays the foundations of the metropolis of her kingdom, building the first houses herself. She then gives birth to their first inhabitants, whom she feeds and nurses without assistance. "At length she receives the reward of her perseverance and labour, and, from being a solitary unconnected individual, in the autumn is enabled to rival the queen of the hive in the number of her children and subjects, and in this edifice which they inhabit—the number of cells in a vespiary, sometimes amounting to more than 16,000, almost all of which contain either an egg, a grub, or a pupa, and each cell serving for three generations in a year; which, after making every allowance for failures and casualties, will give a population of at least 80,000. Even at this time, when she has so numerous an army of coadjutors, the industry of this creature does not cease, but she continues to set an example of diligence to the rest of the community. If by any accident, before the other females are hatched, the queen-mother perishes, the neuters cease their labours, lose their instincts, and die." (Kirby and Spence.)

The community of wasps and its nest are called a vespiary. There are several hundred females in a large vespiary, few of which survive the winter. The survivors fly about in spring actively engaged in preparations for their future colonies. Once established, they never quit the nest. In their youth they emerge from the pupa towards the end of August, and at the same time with the males. They pair in September and October. The males are about equal in number with the females. Their habits are industrious, and not like those of drones, luxurious and lazy. They are the street-sweepers and undertakers of their city. They carry off the rubbish and the bodies of the dead, which, if too heavy for their strength, they quarter and carry away piecemeal. Their lives are peaceful, and they die a natural death at the close of the year, when the cold destroys both them and the workers.

The neuters are the most numerous and busiest class of the vespine community. They are the architects, soldiers, and commissaries of the state. They build the nest, gather provisions, regulate the nurseries, and revenge insults. They ramble everywhere with impunity, and all provisions are to their taste. They levy contributions wherever they can, and fight for their spoil if disturbed. Robbers and

ferocious enemies of the rest of the world, they are faithful servants of the commonwealth of which they are members. The food they collect is shared among all with impartial justice. The worker having brought home his spoil, perches on the top of the nest amid his assembled compatriots, and disgorging the sweets he has collected, fairly distributes them. When not occupied on foraging expeditions, the neuters are employed in the enlargement and repair of the nest. Celerity and order prevail in all their operations. Each of the masons has his allotted space, and neli or an inch and a half in extent, wherein he conducts his plastering occupation, his mouth serving as a hod, carrying a ball of ligneous fibre, previously torn by his powerful jaws from gate-posts, wood-hacks, and neighbouring trees. This fibre, kneaded together and moistened with saliva, is made into a paper, of which are constructed the combs, each made up of a number of hexagonal cells opening downwards. The outside of the whole nest is coated with foliaceous layers. It is probable that the substance of the comb is made from the scrapings of sound wood; that of the envelope from a mixture of sound and decayed. The nests of Tree-Wasps are finest and closest in texture, which is necessary, since they are so much more exposed to the vicissitudes of the weather than those which are buried in the ground. Some foreign species construct their nests of a solid and thick pasteboard, impenetrable to the rain; others diversify the outside of their habitations with conical knobs of various shapes and sizes, supposed to be defences against their larger enemies, and construct pent-roofs to protect the entrance from the wet, the entrance-hall being so twisted as to prevent the invasion of hostile insects. The cells of the comb of the common English Wasp are brown, and coarse in texture; but where the larvæ have spun their cocoons, they are found lined with a white and semi-transparent paper, fashioned on the mould of the cell, and probably made by the larvæ themselves.

Wasps have sentinels placed at the entrances of their nest to give an alarm in case of danger. If these guards are seized and destroyed, the rest do not attack. Mr. Knight observed that if a nest of wasps be approached without alarming the inhabitants, and all communication be suddenly cut off between those out of the nest and those within it, no provocation will induce the former to defend it and themselves. But if one escapes from within, it comes out angrily, as if commissioned to avenge the wrong, and will sacrifice its life in defence of the community.

(Westwood, *Modern Classification of Insects; Introduction to Entomology*.)

VESUVIAN. [IDOCRASE.]

VETCH. [VICIA.]

VETCH, HORSE-SHOE. [HIPPOCREPIS.]

VIBRIO. [INFUSORIA.]

VIBURNUM, a genus of Plants belonging to the natural order *Caprifoliaceæ*. The species consist of shrubs with opposite petiolate leaves and corymbose flowers. The limb of the calyx is 5-cleft, permanent; the corolla rotate, subcampanulate, and tubular; the fruit a berry, ovate or globose, with 1 seed by abortion, and crowned by the calycine teeth. The species are natives of Europe, America, and Asia, and are of easy culture in British gardens. Some of them were known to the Greeks and Romans, though the species have not been always identified.

V. Tinus, the Laurustinus, has ovate-oblong quite entire permanent leaves, with the veins beneath furnished with glandular hairs; the corymbs flat; the flowers white, rose-coloured before expansion; berries dark-blue. This plant, now so common throughout Europe, and the most general inhabitant of the gardens of Great Britain, is a native of the south of Europe and the north of Africa.

All the varieties of Laurustinus are hardy shrubs, are evergreen, and bear the climate of Great Britain well; most of them blossom from November till April, and sometimes during May and June.

V. Lentago, the Lentago, or Tree-Viburnum, has broad ovate-acuminate sharply serrated glabrous leaves; petioles with narrow curled margins; terminal sessile corymbs; white flowers, and black fruit. It is a native of North America, and is found in hedges and on the borders of woods from New England to the Carolinas and also in Canada.

V. Lantana, the Wayfaring-Tree, has cordate-rouded finely-serrated leaves, clothed beneath, but more sparingly above, with a stellate mealy pubescence; the cymes pedunculate, broad, flat, consisting of numerous white flowers. This plant forms a shrub or low tree, and is a native of Europe and the west of Asia, in low woods and hedges, and chiefly on calcareous soils. It is not uncommon in Great Britain.

V. Opulus, the Guelder Rose, or Snow-Ball, is a glabrous plant, with broad 3-lobed acuminate unequally serrated veiny leaves; petioles beset with glands towards the top, and several oblong leafy appendages lower down; flowers of a white colour arranged in cymes, the lateral flowers dilated, flat, and without stamens or pistils; the berries elliptical, bright-red, very juicy, bitter, and nauseous. It is a native throughout Europe, and is especially frequent in Britain and Sweden.

V. Oryococcus, the Cranberry Guelder Rose, has 3-lobed acute 3-nerved leaves; the lobes divaricate, are acuminate, and coarsely and distantly serrated; the petioles glandular; the cymes of white flowers radiant; the berries sub-globose, red, and very much resembling cran-

berries. This plant is a native of North America, on the mountains of New York and New Jersey, and throughout Canada to the arctic circle.

(London, *Arboretum et Fruticetum Britannicum*.)

VICIA, a genus of Plants belonging to the natural order *Leguminosae*. The species are usually climbing herbs, with abruptly pinnate leaves, with many pairs of leaflets; the common petiole terminating in a tendril at the apex, which is mostly branched; the stipules are semisagittate in form, and the peduncles axillary, 1- or many-flowered; the calyx is tubular, 5-cleft or 5-toothed, the two upper teeth shortest; the corolla papilionaceous; the stamens diadelphous; the style filiform, being at right angles with the ovary, villous on the upper side, and on the under side beneath the apex; the legume 1-celled, many-seeded, oblong; the seeds with a lateral oval or linear hilum. The species of this genus are very numerous.

V. sativa, Common Vetch, or Tarc, has leaves with tendrils; the leaflets 6-10, obovate, mucronate; flowers usually twin, sessile; calyx cylindrical; a style bearded at the apex; compressed oblong somewhat torulose reticulated erect legumes, with smooth globose seeds. This plant is a native throughout Europe, and its extensive cultivation diffuses it more abundantly. It is also found in North America, about Fort Vancouver.

V. biennis, Biennial Vetch, has about 12 lanceolate glabrous leaflets, furrowed petioles, and many-flowered peduncles hardly longer than the leaves. This plant is a native of Siberia, and is very hardy, continuing green throughout the winter, and furnishing an early fodder.

V. cracca, Tufted Vetch, has many-flowered peduncles longer than the leaves; flowers imbricate, crowded, of a fine purple colour, and nearly entire semi-sagittate stipules. It is a native of Europe, and is common in Great Britain in bushy places.

V. pisiformis, Pea-like Vetch, is a quite smooth plant with 3-4 pairs of ovate leaflets; ovate semi-sagittate toothed stipules, with many-flowered peduncles; and oblong reticulately-veined legumes. It is a native of the south of Europe, in woods, and is cultivated on account of its seeds.

V. sepium, Bush-Vetch, has flowers mostly in fours, somewhat stalked; upright glabrous legumes; ovate obtuse leaflets. It is a native of Europe, and is common in Great Britain in woods and shady places. It shoots early in the spring, and would answer for feeding cattle; but an objection to its cultivation exists, as its seeds are liable to the attacks of the larvæ of a species of *Attelabus*. It has been recommended to be sown among clover for mowing.

V. sylvatica, the Wood Vetch, has many-flowered peduncles longer than the leaves, elliptico-oblong mucronate leaflets, and innate stipules deeply toothed at their base. It is a native of Europe in mountain woods, and is abundant in the north of England and Scotland. It has numerous large white flowers streaked with bluish veins, and is the handsomest of the British species. Its stems are from 3 to 6 feet high, climbing by means of its branching tendrils. It has been recommended as a valuable plant for fodder.

V. lutea, Rough-Podded Yellow Vetch, has sessile solitary flowers; the standard glabrous; the legumes reflexed, hairy; the stems diffuse; the stipules coloured. It is a native of the south of Europe. In Great Britain it is occasionally found on stony ground, especially near the sea. Its stems are from 6 to 12 inches high, and it has long yellow flowers.

V. bithynica, Rough-Podded Purple Vetch, has stalked mostly solitary flowers, with rough upright legumes; petioles with two pairs of lanceolate leaflets, and toothed stipules. It is a native of the south of Europe. It occurs occasionally in Great Britain, in gravelly soils, more especially near the sea. It is a prostrate plant with purple and white flowers.

VICO'A, a genus of Plants belonging to the natural order *Compositae*, and sub-tribe *Inuleæ*.

VICUGNA, or **VICUNA**. [LLAMA.]

VIDUA. [PLOCEINÆ.]

VILLARSIA, a genus of Plants belonging to the natural order *Gentianaceæ*, named after Villars, a French botanist. It has a 5-parted calyx; a subrotate corolla with spreading limb, the segments with a flat disc; 2-lobed stigmas, the lobes toothed; 5 hypogynous glands; a 1-celled 2-valved or valveless capsule; seeds naked, or girded with a membranous margin. There are about 16 species of this genus. They are either aquatic or marsh plants, with alternate entire leaves and yellow flowers. They are inhabitants of all parts of the world. One only is a native of Europe.

V. Nymphenoides, Nymphaea-like Villarsia, is a floating plant, with orbicular-cordate leaves; the peduncles single-flowered, and aggregate; the segments of the corolla ciliate. It is a native of Denmark, Holland, Sweden, Germany, Piedmont, and of Siberia. It is found in ditches and slow-running streams. It is also a native of Great Britain, though comparatively a rare plant. It is found in the Thames, in the recesses of the shores near Walton Bridge, near Botley Bridge, Godstow Bridge, and Hinksey Ferry. It occurs also in the fens of Lincolnshire and in Yorkshire. It is a beautiful plant, and may be easily cultivated. It has a large yellow flower, which is curiously plaited. It is a very abundant plant in Holland, frequently covering large tracts of the canals with its beautiful yellow flowers and dark-green leaves.

VILLARSITE, a Mineral whose primary form is a rhombic prism. Colour yellowish-green. Fracture granular. Hardness 3.0 to 3.5. Subtransparent. It is found at Traversella in Piedmont. It contains silica, magnesia, protoxide of iron, protoxide of manganese, lime, potash, and water.

VINA'GO. [COLUMBIDÆ.]

VINCA (from 'vinco,' to bind), a genus of Plants belonging to the natural order *Apocynaceæ*. It has a salver-shaped corolla, with the tube longer than the calyx, and the throat bearded; the segments of the limb flat, oblique, 5-lobed, truncate at the apex; 5 stamens inserted in the throat, inclosed with short filaments. Five or six species of this genus have been described; they are creeping, suffrutescent, or herbaceous plants, with smooth shining opposite leaves, with blue, purple, or white flowers, seated on solitary axillary alternate peduncles. They are natives of Europe, in shady places.

V. major, Greater Periwinkle, has stems rather erect, ovato-acute ciliated leaves; teeth of the calyx linear, subulate, ciliated, and usually with a smaller tooth on each side at the base; the segments of the corolla are broad and ovate. It is a native of the middle and southern parts of Europe, and is apparently wild in many parts of Great Britain, but it may be doubted whether it is an original native of this island. Its flowers are of a fine purple-blue colour, and are larger than those of any other species. The English name, Periwinkle, seems to be derived from the French, *Pervenche*. In Chaucer's time it was called *Perwinke* :—

"There sprang the violet al newe,
And fresh perwinké rich of hewe."

The flowers appear early in spring, and continue open all the summer. It is well adapted for growing on the ground of shrubberies, as well as on the banks of hedgerows, or in any shady place. In olden times great virtues were attributed to the Periwinkle; amongst other things, Culpepper says, "the leaves of the Periwinkle eaten by man and wife together do cause love between them." In Italy this plant is called *Fiore di Morte*, from the practice of making garlands of it in which to bury dead children. It was at one time much used in sorceries and incantations, hence the French still call it *Violette des Sorciers*.

V. minor, Lesser Periwinkle, has procumbent stems; the flowering stems usually erect. It is a native of Europe, in the same situations as the last, and is often found in Great Britain.

VINCULARIA. [POLYZOÆ.]

VINE. [VITIS.]

VIOLA, a genus of Plants, the type of the natural order *Violaceæ*. The sepals are unequal, 5, all more or less drawn out downwards into ear-like appendages, erect after flowering; petals 5, unequal, convolute in aestivation, with 3-nerved claws, the lower one drawn downwards into a hollow spur; stamens 5, approximate or coarctate, inserted on the top of the teeth of a pentagonal 5-toothed torus; the filaments dilated at the base, oblong or triangular, bearing the anthers low down; lobes of anthers spreading at the base; the two anterior stamens bearing on their back two nectariferous lancet-shaped round or linear appendages, which are drawn in within the spur. The species of this genus are exceedingly numerous.

V. odorata, Common Sweet Violet, has no stem; a hooked naked stigma; crenated smoothish roundish-cordate leaves; ovate obtuse sepals, the two lateral petals with a hairy line; the spur very blunt; the capsules turgid, hairy; the seeds turbinate, whitish; the stoles creeping, long, rooting. This plant is a native throughout the whole of Europe, and in Siberia and China. It is common in England, but is a rare plant in Scotland and Ireland. Wherever this plant grows its delicious scent has made it a great favourite.

V. hirta, the Hairy Violet, has no stem, the whole plant villous or pubescent. It is found throughout Europe, and is not uncommon in England, though rare in Scotland.

V. canina, Dog's Violet, has an herbaceous ascending channelled stem and cordate acute leaves. The flowers are blue and scentless. It is a native of Europe and America.

V. palustris, the Marsh Violet, has jointed scaly roots; a marginate stigma; smooth cordately kidney-shaped leaves; broad ovato-acuminate stipules. It is more abundant in Scotland than England.

V. lactea, Cream-Coloured Violet, has an ascending stem, with ovato-lanceolate glabrous leaves, deuteate stipules, and acuminate bracts. It is a native of boggy heaths in Switzerland, France, and Britain. It is by some considered only a variety of *V. palustris*. *V. biflora* is a native of Europe and North America, and has a 2-flowered stem with small yellow flowers, the lip being streaked with black.

V. tricolor, Three-Coloured Violet, Heart's-Ease, or Pansy, has a somewhat fusiform root; diffuse branched stems; lower leaves ovato-cordate, deeply crenate; runcinately pinatifid stipules, with the middle lobe crenate; spur thick, obtuse; nectaries linear. This plant is a native of cultivated fields and gardens throughout Europe, Siberia, and North America. The petals vary exceedingly in colour and size, and this tendency has been taken advantage of by the floriculturist for producing varieties of this flower, and there is no flower that has received more attention than the Pansy. [PANSY, in ARTS and SC. DIV.]

V. lutea, Yellow Mountain-Violet, or Yellow Pansy, has a fibrous slender root; simple triangular stems; ovate oblong crenate fringed

leaves; lyrate subpalmato-pinnatifid leaflets. This plant is a native of moist mountainous pastures in Wales, the north of England, and Scotland. The other British species are *V. sylvatica* and *V. stagnina*.

In their geographical distribution the species of violet are materially influenced by climate. "The species from tropical countries," says Professor F. Forbes, "are mostly from localities where the influence of elevation has neutralised or modified the climatical influence. The various sections of the genus have geographic centres, as may be seen in the congregations of the allies of *V. hirta* in North America, and of those of *V. tricolor* in alpine Europe. North America may be looked upon as the capital of the whole genus, since we find there representatives of all its subdivisions. In the following table the distribution of 75 species, according to the form of their nectaries, is exhibited:—

Nectaries.	Europe.	Asia.	Africa.	America:		Australia.	Total.
				North.	South.		
Lancet-Shaped .	19	4	1	22	1	1	48
Rotund . . .	2	0	0	1	0	1	4
Linear . . .	12	4	1	6	0	0	23

VIOLACEÆ, Violet-Flowers, a natural order of Exogenous Plants. It has the following essential characters:—Sepals 5, persistent, with an imbricate aestivation, usually elongated at the base. Petals 5, hypogynous, equal or unequal, usually withering, and with an obliquely convolute aestivation. Stamens 5, alternate, with the petals occasionally opposite them, inserted on a hypogynous disc, often unequal; anthers bilocular, bursting inwards, either separate or cohering, and lying close upon the ovary; filaments dilated, elongated beyond the anthers; two in the irregular flowers, generally furnished with an appendage or gland at their base. Ovary 1-celled, many-seeded, or rarely 1-seeded, with 3 parietal placentæ opposite the three outer sepals; style single, usually declinate, with an oblique hooded stigma. Capsule of 3 valves, bearing the placentæ in their axis. Seeds often with a tumour at their base; embryo straight, erect in the axis of fleshy albumen. (Lindley.) The species are herbs, undershrubs, or shrubs with alternate rarely opposite leaves, simple, usually involute before expansion, and all furnished with stipules. The flowers are erect or drooping, axillary, seated on peduncles, which are 1-flowered, solitary, or numerous, sometimes branched.

Violaceæ are related to *Polygalaceæ*, *Dorseraceæ*, and *Passifloraceæ*. The order is divided into two tribes, *Violæ* and *Alsodineæ*. The former chiefly inhabit Europe and America; the latter, with the exception of the genus *Pentaloba*, are natives of South America and Africa. This order embraces 11 genera and 300 species.

Viola pedata.

1, entire plant; 2, corolla and calyx of flower removed, to show the anthers and nectary; 3, stamen; 4, section of capsule; 5, section of seed, showing the embryo.

All the *Violaceæ* possess in a greater or less degree emetic properties, which reside principally in their roots; the principle on which this property seems to depend has been separated by Boullay from some species of *Viola*, and has been called *Violina*. *Viola odorata* is admitted into the Edinburgh and Dublin Pharmacopœias for the purpose of making a syrup of the flowers, which is used on account

of its scent, and is administered to children as a laxative; it is also used as a test of acidity and alkalinity, being rendered green by alkalis and red by acids. [CEPHARLIS; IONIDIUM; VIOLA.]

VIOLET. [VIOLA; VIOLACEÆ.]

VIPER. [VIPERIDÆ.]

VIPER'S BUGLOSS. [ECHIUM.]

VIPER'S GRASS. [SCORZONERA.]

VIPERIDÆ, a family of Snakes, which are thus characterised by Dr. J. E. Gray:—Face without any suborbital pit on the side; upper jaw toothless, with fangs in front; rostral shields broad, band-like; scales keeled (except in *Acanthophis*); tail short, tapering.

The following synopsis of the genera is given in the 'British Museum Catalogue':—

I. Head depressed, rounded on the sides, covered with acutely-keeled scales.

a. Nostrils large, subsuperior, anterior, in the centre of a ring-like shield, edged with a large scale above. *Clothonina*.

1. *Daboia*.—Eyes convex, pupil round; head elongate; scales regularly keeled; nasal shield smooth in front. It is found in India.

2. *Crotho*.—Eyes convex, pupil oblong, erect; head short, broad, scales keeled, ending in a spine; nasal shield interrupted by a small shield in front. It is found in Africa.

b. Nostrils small, subanterior, sublateral. *Cerastina*.

3. *Cerastes*.—Subcaudal plates 2-rowed; nostrils lunate on the hinder part of a small nasal plate; eye-lid of males horned.

4. *Echis*.—Subcaudal plates 1-rowed; nostrils minute in suture of two small scales; the anterior frontal shields minute, smooth; pupil round.

II. Head more or less shielded; nostrils anterior, lateral.

a. Head flat-topped, high on the sides, shielded in front; nostrils in the middle of a shield; tail-end simple; subcaudal plates 2-rowed. *Viperina*.

5. *Vipera*.—Superciliary shield distinct; rest of the head covered with small smooth plates; nose more or less recurved.

6. *Pelias*.—Vertebral, occipital, and superciliary plates distinct; front of head with small shields; nose blunt.

b. Head ovate, rounded on the sides, crown entirely shielded; nostrils between two plates; tail-end simple; subcaudal plates 2-rowed. *Sepedonina*.

7. *Sepedon*.—Scales keeled; loreal shields none; one anterior and three posterior ocular shields; subcaudal shields 2-rowed.

c. Head depressed, shielded, prominent over the eyes; nostrils between two shields; tail ending in a recurved spine; subcaudal plates 1-rowed. *Acanthophina*.

8. *Acanthophis*.—Head-shield rather scale-like; loreal none.

III. Head dilated, depressed, covered with acutely-keeled scales, rounded on the sides.

a. Nostrils large, subsuperior, anterior, in the centre of a ring-like shield, edged with a large scale above. *Clothonina*.

The family contains 9 genera and 20 species, of which 2 genera and 4 species are from Asia, 5 genera and 12 species from Africa, 2 genera and 3 species in Europe, and 1 genus and 1 species from Australia.

One of the most characteristic features of this group of animals is the possession of glands which secrete a poison with which they destroy their prey.

The machinery which enables the venom-snakes to inflict the wounds by which they kill is seen in the accompanying plates.

Skull of Rattlesnake: profile.

Tooth and poison-gland of *Trigonocephalus mutus*.

a a, poison-gland; b, duct; c, fang; the letter indicates the position of the slit, from which the poison passes into the wound.

We now proceed to describe a few of the forms illustrative of this poisonous family.

Pelias Berus, Merr.; *Vipera*, Ray; *V. vulgaris*, Latr.; *V. communis*, Leach; the Common Viper.

"The head," says Mr. Bell, in his 'British Reptiles,' "is somewhat depressed, almost oval, slightly widening behind the eyes. Gape as long as the head, extending behind. No teeth in the upper maxillary bones excepting the poison-fangs; a row of small teeth in the palatine bone on each side. Neck rather smaller than the back of the head, from which the body increases to nearly the middle of the entire length; the rest of the body to the vent scarcely diminishing; the tail becoming almost abruptly smaller, and tapering to its extremity, which is pointed: the tail varies in proportion to the body, but is generally not more than one-eighth of the total length, and in some even less. The head is covered with small squamose plates, which in some specimens are regularly formed and symmetrically placed; but in others they are very irregular. There are three which are larger than the others, namely, the vertical and the pair of occipital plates. The scales of the back and sides are semioval or somewhat lanceolate, imbricated, and distinctly carinated. They are disposed in eighteen series. The plates of the abdomen have nothing particular in their form; they vary in number, but usually consist of about one hundred and forty to about one hundred and fifty, and those of the tail are about thirty-five pairs.

Head of the Viper. (Bell.)

"The general ground-colour varies considerably. In some it is nearly olive, in others a rich deep brown, and in others a dirty brownish-yellow; and when in high health, and shortly after having cast the skin, the surface is slightly iridescent in particular lights. A mark between the eyes, a spot on each side of the hinder part of the head, and a zigzag line running the whole length of the body and tail, formed by a series of confluent rhombs, as well as a row of small triangular spots on each side, all of a much darker hue than the ground-colour of the body, and frequently almost black. I have a specimen in my collection which I received alive from Hornsey Wood, the ground of which was almost perfectly white, and all the markings jet-black. The under parts are plumbeous in some, with lighter or darker spots; in others wholly black."

Common Viper or Adder (*Vipera communis*).

This is, not improbably, the *Exis* of Aristotle and the Greeks, and the *Vipera* of Virgil ('Georg.,' iii. 417), Pliny ('Nat. Hist.,' viii. 39; x. 42; xi. 37) and the Romans. It is the Marasso of the Italians; Vipere of the French; Hugg-Orm of the Swedes; and Adder (anciently written Nedre, and later Eddre, with the loss of the initial *n*, from the Anglo-Saxon Nædre) of the country people in many parts of England and Scotland.

This reptile is found in Europe generally, from the north of Russia to the south of Italy and Spain; in England and Scotland, but not in Ireland.

From a very early period there appears to have been a notion that the female Viper, in order to take care of her young, swallows them. This is a question not easily answered, and it has been warmly disputed. There is no physiological reason against it. The young might live in such a situation for some time: it is well known that frogs will live and cry in the stomach of a serpent. But the evidence

of the viper-catchers is strong against the fact, and we have never met with any one who could state that he had actually seen the young enter or issue from that retreat. It is not improbable that when female vipers in the last stage of pregnancy have been surprised, and on being opened have disclosed living young, the spectators, not aware of the extreme thinness of the membrane which incloses them, and which a very slight pressure will suffice to rupture, have leaped to the conclusion that the young had entered the mouth for protection.

When a viper is about to strike, it is generally more or less coiled, and elevates the head and neck, which are drawn backwards, the former in a horizontal position. The head is then suddenly darted at the object of attack, and the erected tooth plunged into it and withdrawn with a motion almost too quick for the eye to follow. Unless very much irritated the serpent will not immediately repeat the bite, as if conscious that time is required for the renewal of the poisonous secretion, so as to make it sufficiently virulent.

We are not aware of any well-authenticated case of a person bitten by a viper terminating fatally; but we would by no means insure a person so wounded in the heats of summer or autumn, especially if the wound be inflicted on a naked part, and if he be of a bad habit of body. The remedy used by viper-catchers is to rub olive-oil on the part wounded, over a chafing-dish of coals. They also take it internally. Some of them suffer themselves to be bitten by vipers full of 'sweltered venom,' confident in their remedy. Such cases will be found in the work of Dr. Mead, who proved the innocence of the poison when swallowed, by taking it himself without the slightest ill effect, an example not to be rashly followed, for any recent injury to the gums, or the skin of the mouth or throat generally, would render such an experiment extremely hazardous from the vascularity of the part. Great medical virtues have been attributed to vipers.

The lingering belief in the wonderfully invigorating qualities of 'viper broth' is not yet quite extinct in some places. Pliny, Galen, and others praise the efficacy of viper flesh in the cure of ulcers, elephantiasis, and other disorders arising from a corrupt state of the system. By the ancients the animal was generally served to the patient boiled like fish, as being more efficacious than when taken in the form of a powder or other dried state. Sir Kenelm Digby's beautiful wife was fed on capons fattened with the flesh of vipers.

Open copses, dry heaths, newly-cleared woodlands, and sandy wastes are the usual haunts of the viper, which, in winter, is frequently found in its hybernaculum, intertwined with several of its own species, and in an almost torpid state. These conglomerations may have given rise to the mode in which the celebrated Ovum Anguinum was produced. Pliny indeed ('Nat. Hist.,' xxix., c. 3) attributes its production to snakes convoluted together in the summer, and notices the statements of the Druids with regard to this mystic creation. Mason has not omitted to take advantage of this tradition in his 'Caractacus,' where the Druid sings—

"From the grot of charms and spells,
Where our nutron sister dwells,
Brennus, has thy holy hand
Safely brought the Druid wand,
And the potent adder-stone
'Gender'd 'fore the autumnal moon?
When in undulating twine
The foaming snakes prolific join."

Our modern druidesses gives much the same account of the Ovum Anguinum, Glaiu Neidr, as the Welsh call it, or the Adder-Gem, as the Roman philosopher does, but seem not to have so exalted an opinion of its powers, using it only to assist children in cutting their teeth, or to cure the chin-cough, or to drive away an ague. These heads are made of glass, and of a very rich blue colour: some are plain, others streaked: we say nothing of the figure, as the annexed plate will convey a stronger idea of it than words.

Adder-Stones. (Pennant.)

Vipera (Cerastes) caudalis, Smith (*Vipera ocellata*, Smith), is a species described by Dr. Andrew Smith, and is found in South Africa.

Dr. Smith says of this snake, that, though generally inactive, it is by no means so when injured: its movements are then performed with activity; and when once it seizes the obnoxious object, it retains its

hold with great determination, and some considerable exertion is often required to detach it.

Head and Tail (under side) of *Vipera (Cerastes) caudalis*. (Smith.)

The head is distinct; the body thick in proportion to its length; the tail short, tapered, and pointed. Angles of the jaws very divergent, giving greater width to the hinder part of the head, the anterior portion of which is narrower. Nose rounded; nostrils near its apex, each in the centre of a thick projecting scale. Eyebrows arched, each armed near its middle with a slender pointed slightly-recurved spine, about a line or a line and a quarter in length. Scales of anterior part of the head, particularly round the eyes, very small; those between and immediately behind the nostrils imperfectly carinated; on the hinder part of the head they are oval, as on the body, and distinctly carinated. On the back and sides they are arranged in longitudinal rows; and from the points of each row overlapping the base of those immediately behind them, the carinations form continuous ridges, about twenty-seven in number generally.

Vipera (Cerastes) caudalis. (Smith.)

Echidna inornata (Smith) is another African species.

Back and sides dark yellowish-brown; belly brownish-yellow, sparingly sprinkled with brownish dots; tail above, indistinctly marked with dull brown spots or bars. Head oblong, heart-shaped. Length 13½ inches. (Smith.)

Echidna inornata. (Smith.)

Dr. Smith notices the fact that the *Vipers* and one or two species of *Elaps* are the only snakes of South Africa which permit themselves generally to be closely approached without evincing any apparent concern. The others manifest a disposition to act on the offensive

or to fly: even an unusual noise, without its cause being visible, is sufficient, he remarks, to insure the retreat of the innocuous ones.

The different species of *Naia* and the *Elaps lubricus* (Merr.) are, he observes, always ready for the fight; and when their haunts are invaded they often advance upon the intruder with the head and anterior part of the body almost perpendicular, the neck expanded, and an expression sufficiently indicative of the malignant purpose they have in view. "To witness such a proceeding," says Dr. Smith in continuation, "once fell to my own lot. Walking in the vicinity of Graham's Town, I happened to excite the attention of a *Naia Hamachates*, which immediately raised its head, and warned me of my danger by the strength of its expiration; it then commenced an advance, and, had I not retired, I should in all probability have suffered, provided I had not been fortunate enough to disable it, which possibly would not have happened, considering that the species, in common with others of the same genus, is extremely active. Even though I retired I was not satisfied the danger was past, as the flight of this snake's enemy does not always put a stop to its advance when once commenced."

Dr. Smith figures three varieties of *Naia Haje* in his 'Zoology of South Africa' and the young state of the serpent, with the synonyms *Echidna flava*, Merr., *Naia nigra*, Smith, Geel Copell, Bruin Copell, and Spuugh-Slang of the Cape Colonists.

Naia Haje (young). (Smith.)

Dr. Smith remarks that if this reptile be specifically different from *Naia Haje* of Northern Africa, he had not, after closely comparing them, been able to discover the differences which, in his opinion, could justify him in regarding them as distinct.

Spuugh-Slang (*Naia Haje*).

Colour uniform livid blackish-brown, the livid tinge strongest on the under parts, forming almost a purplish slate-colour, which is very dark and shining towards the head. (Smith.)

The variety most rarely met with, according to Dr. Smith, is the Spuugh-Slang (Spitting-Snake) of the colonists, so named from its

supposed power of ejecting its poison to a distance. All the Cobra-di-Capellas of Southern Africa, he remarks, distil poison from the points of their fangs when they are much irritated, and are able to eject a portion of it beyond the mouth by a forcible expiration; but that any power greater than that is possessed by the Spuugh-Slang, Dr. Smith is not disposed to believe: the contrary nevertheless is, he allows, strongly maintained both by the European and native inhabitants.

Acanthophis tortor, Less. *A. Brownii*, Lesch; *A. antarctica*, Wagler; is a native of Australia, where it was first noticed by Mr. Robert Brown, the celebrated botanist. The colonists call it the Death Adder and the Black Snake.

Acanthophis tortor, Less. (*Acanthophis Brownii*, Leach?).
a, head. (Lesson.)

Head and tail of *Acanthophis Brownii*. (Leach.)

M. Lesson states that this snake is very much diffused in Australia where the colonists dread it much in consequence of the mortal wounds which it inflicts. Its bite, he says, has often killed convicts in less than a quarter of an hour, if the reports of the inhabitants may be credited. It is, he adds, very common in the small woods and sandy heaths which surround Botany Bay, where M. Lesson states that he has often seen it in his excursions.

VIPERINA. [VIPERIDÆ.]

VIREONINÆ. [MUSCICAPIDÆ.]

VIRGILIA, a genus of Plants belonging to the natural order *Leguminosæ*, named after Virgil the Roman poet.

VIRGIN'S BOWER. [CLEMATIS.]

VIRGINIAN SNAKE ROOT. [POLYGALA.]

VIROLA SEBIFERA, a large tree of Guyana, which belongs properly to the genus *Myristica*, and is in fact by some called Nutmeg of Cayenne, and has the same properties as many of the other species of that genus. When incisions are made into the bark, a reddish glutinous juice exudes, which, when fresh, is used as a caustic, and which concentrates in time. The mace is of a red colour, and within it the kernel is of a whitish colour, which, when powdered and put into boiling water, yields a yellowish-coloured fatty substance which swims on the surface; it is caustic in taste, and has a slight odour of nutmeg. In the country candles are made of it; hence Europeans call the tree *Porte Suif*.

VISCUM, a genus of Parasitical Plants belonging to the natural order *Loranthaceæ*, of which one species is found wild in this country. *V. album*, the Mistletoe, is in many respects a production of great interest to the physiologist. The seeds in germination seem to offer an exception to a general law, that the radicle of the embryo shoots downwards, and the plumule upwards; for it is found that the radicle of the Mistletoe invariably turns itself down upon the body to which it is attached, whatever may be the position of the surface of that body with respect to the earth. For instance, if a cannon ball, to which mistletoe-seeds are glued on all sides, be suspended by a cord some distance from the earth, both the upper and under seeds, as well as those at the sides, all direct their radicle to the surface of the ball. This property ensures their growing upon the branches of trees, to whatever side they may happen to stick.

In fixing itself upon a branch, the embryo of the Mistletoe curves its radicle down upon the bark, and then adheres firmly to it, and it is a twelvemonth before the plumule begins to extend; this may be to give the radicle time to pierce the bark and introduce itself below the liber, where it expands and acts the part of a root by attracting thence the fluids which are necessary for the support of the parasite.

It is not a little remarkable that in the structure of its ovary this plant, and others of its order, should offer the singular fact of the ovule not existing at the time of impregnation, nor appearing till from six weeks to two months later.

The fruit, which is covered with a viscid pulp, is made by the Italians, and even in Herefordshire, into a kind of birdlime; and as it is a favourite food of the large or Missel Thrush, it is thought to have given rise to the proverb, '*Turdus malum sibi cacat*.'

The plant is not of any known use to man, and is of popular interest chiefly as having been connected with Druidical superstitions. The Mistletoe of the Druids was exclusively that found upon the oak, and was possibly so much valued because of its rarity; for its appearance on that tree is now so rare, that many persons have believed the Mistletoe of the Druids either to have been some other plant or to have had no real existence.

(Loudon, *Arboretum Britannicum*, vol. ii.)

VISION. [EYE.]

VISMIA (in honour of M. de Visme, a Lisbon merchant), a genus of Plants belonging to the natural order *Hypericaceæ*. The calyx is 5-parted, the petals 5, usually villous on the inside.

V. Guianensis is a small tree with a stem about 8 feet high, the leaves ovate, lanceolate-acuminate, dilated at the base, rufous beneath, smooth above, filled with transparent dots. The bark when wounded yields a gum-resin, which when dry becomes hard, and resembles gamboge. The leaves and fruit likewise yield a similar secretion. It is used in medicine as a purgative, in doses of from 7 to 8 grains.

VITACEÆ, or **VINIFERÆ**, *Vinevorts*, a natural order of Plants belonging to Lindley's aluminous group of Polypetalous Exogens. The species of this order are composed of sarmentose and climbing shrubs, and hence the order is sometimes called *Sarmentaceæ*, of which the Grape-Vine is the type. Kunth has named the whole order *Ampelideæ*, from *ἀμπελος*, the vine. Jussieu, in the first edition of the '*Genera Plantarum*,' called this order *Vites*. The calyx is small, with an entire or toothed margin; the petals 4 or 5, inserted on the outside of the disc, turned inwards at the edge in aestivation in a somewhat valvate manner, and the apex often inflexed; the stamens are equal in number to the petals, and placed opposite them, sometimes sterile by abortion; the filaments are distinct, or slightly cohering at the base; the anthers ovate and versatile; the ovary is superior, 2-celled; the style single, very short; the stigma simple; the ovules definite and erect; the fruit a globose berry; the peduncles are racemose, thyrsoid, corymbose, cymose or umbellate, opposite the leaves, and are sometimes changed into tendrils.

This order has acid properties, in common with *Grossulaceæ* and *Berberaceæ*. It has also affinities with *Umbelliferae* and *Geraniaceæ*.

This order includes 6 genera, which for the most part inhabit the warmer parts of the northern temperate zone, and are found in both the Old and New worlds. Most of them are natives of Asia, one of Australia, and none in Europe. The most characteristic property of this order is acidity, which is most fully developed in the Grape-Vine. [VITIS.] Some of the species of *Cissus* are used in medicine.

VITALITY, a term equivalent to that of Life, and applied to the functions performed by living bodies, that is, plants and animals. Linnæus defined the three kingdoms of nature as follows:—Minerals grow; Plants grow and live; Animals grow, live, and feel. Here the fact of living is made to distinguish between minerals and plants, and the inquiry is naturally made for a definition of life. It is often assumed to be a set of actions under the controlling influence of a vital principle, but, as such a principle has never been demonstrated, it must be regarded only as an assumed cause. Some writers have supposed that all the phenomena of life may be resolved into the action of chemical and physical forces acting upon special forms of matter, and that in plants and animals are presented the results of chemical and physical activity in forms in which it does not exist amongst minerals. Coleridge, in his 'Idea of Life,' contends that the collective activities of the material universe is as much a life, and its parts as much entitled to be regarded as living, as a plant in its special organs.

Setting aside however the idea of a vital principle, or confining this term to the force which regulates and produces the specific form in each individual animal or plant, and which is then applicable as well to minerals, there are a certain set of phenomena in plants and animals to which the term 'vital' seems especially applicable. This term may be thus applied without in any manner assuming the existence of any force independent of those which are known to influence all matter upon the surface of the earth.

Thus, the growth and reproduction of cells may be regarded as a vital process; also the contractibility of the muscular tissue, and the sensibility of the nervous tissue. These processes are called collectively Vital Processes. The force by which cells grow has been called the Organising Force, the Plastic Force, the Assimilative Property, and the Metabolic Property. The contractibility of the muscles has been properly called Muscle-Force, whilst the sensibility of the nerves has been called Nerve-Force.

That these forces are dependent on physical forces is seen in the fact that plant-cells will not grow without light. Muscle-force and nerve-force are not producible but by the assimilation of materials that have been formed by chemical actions produced by heat and light.

The natural philosopher has demonstrated that electricity, galvanism, and magnetism, are different manifestations of the same force. He has rendered it probable that motion, heat, light, and chemical affinity, are also convertible forces. The physiologist has followed this train of thought, and rendered it probable that, with regard to muscle-force and nerve-force, they are but differentiations or other manifestations of the physical forces. Muscle-force and nerve-force depend upon the destruction (chemical change) of cells which are formed out of materials (protein) which have been formed by the influence of heat and light upon the carbonic acid and ammonia supplied to the cell of the plant. A certain amount of protein is the expression of a certain amount of chemical change, and this again in decomposition is the expression of the amount of vital force, which a part composed of protein will exhibit. Vital phenomena are found to be but the expressions of chemical and physical change, and result in one or other of the physical forces. This view of the nature of vitality does not lead to materialism, as the consciousness of man exists independently of the physical changes which go on in his body, and the character of his mind is formed in virtue of its retaining impressions from the ever-active changes which go on in his body through the agency of the vital forces. [MUSCLE; NERVOUS SYSTEM; ANIMAL KINGDOM; MOTIONS OF PLANTS; VEGETABLE KINGDOM; CELLS.]

(Matteucci, *Electro-Physiological Researches*, in *Philosophical Transactions*; Matteucci, *On the Physical Phenomena of Living Beings*; Grove, *On the Correlation of the Physical Forces*; Reynolds, *Objects and Scientific Position of Physiology*; *British and Foreign Medical Review*, vol. xxx.)

VITEX, a genus of Plants belonging to the natural order *Verbenaceæ*. It has a short campanulate 5-toothed calyx. The corolla is irregular, somewhat labiate, divided into 5 lobes. Stamens 4, didynamous, inserted into the corolla. Ovary superior, roundish; style the length of the stamens; 2-pollinated and diverging stigmas. The fruit is a globular berry, a little hard, with its base covered by the calyx, and divided into four single-seeded cells.

V. agnus-castus, the longest-known species, and a native of the south of Europe, has digitate leaves of 5 or 7 nearly entire leaflets, something resembling those of the hemp-plant, and it forms a shrub of about 12 feet in height. The flowers are arranged in spiked whorls, and have an agreeable fragrance. The fruit is globular, rather smaller than black pepper, with an acrid and aromatic taste, whence it is called *Petit Poivre* and *Poivre Sauvage* in the south of France. It was well known to the ancients, and forms the *Piper agrestis* of some authors. In India the fruits of the species *V. triphylla* and *V. Negundo*, which are indigenous there, have the same properties ascribed to them, and are called *Filfil Burræ* (Wild Pepper). The ancients considered the *Vitex* anti-aprodisiac, but the berries, from their warm aromatic taste, must be possessed rather of stimulant properties.

VITIS, a genus of Plants, the type of the natural order *Vitaceæ*. It possesses the following characters:—Calyx usually 5-toothed; petals 5, cohering at the top, resembling a calyptra, separating at the

base and deciduous; 5 stamens; style none; berry 2-celled, 4-seeded; cells and seeds often abortive. The species are climbing shrubs, with simple lobed, cut or toothed, rarely compound leaves, the thyrsoid racemes of small greenish-yellow flowers. They are found principally in Asia and America.

The best known of the species of *Vitis*, and perhaps one of the most extensively cultivated and useful of plants, is the *V. vinifera*, the Common Vine or Grape-Vine. It is characterised among the other species by possessing lobed, sinuately-toothed, naked or downy leaves. A multitude of varieties of this plant have been recorded, both occurring wild and resulting from its very extensive cultivation.

Grape-Vine (*Vitis vinifera*).

1, cutting, with a bunch of fruit; 2, inflorescence; 3, transverse section of berry in young state; 4, vertical section of the same; 5, section of ripe fruit; 6, section of seed, showing embryo.

Like most extensively cultivated plants, it is very difficult to ascertain of what country the vine is originally a native. It is among the plants of which we have the earliest records in the Books of Moses, and from which it appears to have been made use of in the same manner as at the present day. Although the vine is found in many places wild, it may still be doubted whether it is indigenous there, on account of its frequent cultivation. There can be little doubt of its being truly indigenous in the East, in the district between the Black and Caspian seas. In the forests of Mingrelia and Imeretia it flourishes in all its magnificence, climbing to the tops of the highest trees, and bearing bunches of fruit of delicious flavour. In these districts no cultivation of the vine exists, and the inhabitants seldom harvest the abundance of fruit that is produced. [VINE, in ARTS AND SC. DIV.]

In many spots in France, Germany, Portugal, and Italy, the vine is found wild, but the fruit is very generally of an inferior kind, and it may be doubted whether it is truly indigenous in any parts of Europe.

The cultivation of the vine extends from near 55° N. lat. to the equator, but in south latitudes it only extends as far south as 40°. It is cultivated at various elevations. In middle Germany it ceases from about 1000 to 1500 feet above the level of the sea. On the south side of the Alps it reaches 2000 feet; in the Apennines and Sicily 5000 feet; and on the Himalayas as high as 10,000 feet above the level of the sea. The point of the greatest importance in the ripening of the fruit of the vine is the length of the summer. Thus, although the maximum of summer heat is as great at Moscow as in Paris, yet the vine will not ripen its fruit in the former place, and this arises from the fact that although the greatest heat of the months of June and July are as great as that of Paris, the months of August and

September are several degrees below. Nor will the mean temperature serve as a rule to indicate where the vine may be cultivated. England has a mean temperature as high as many parts of the world, where the vine flourishes in the greatest perfection; but it will be found that although England is warmer than these countries in the winter, it is not so warm in the months of September and October, at which time the vine is ripening its fruit.

The fruit of the vine is used as an article of diet in several ways. Its agreeable sweet acid flavour when ripe has always rendered it a very desirable food when fresh. The ancients also, there can be little doubt, were in the habit of drinking the expressed juice of the grape before fermentation. Grapes are also dried and used under the name of raisins. The drying is generally effected by cutting half through the fruit-stalk whilst they are suspended on the tree. Grapes thus dried are called Muscatel raisins, and are principally brought from Spain and the Levant. There is another dried grape used much in this country, called currants, or Corinths, but which are very different things from the common currant of our gardens, and are the produce of a vine which grows in Zante and Cephalonia. [WINE, in ARTS AND SC. DIV.]

Some of the species of *Vitis* have been introduced into our shruberies and gardens as ornamental climbers.

VITREOUS HUMOUR. [EYE.]

VITRINA, Draparnaud's name for a genus of *Helicidae*.

M. De Ferussac has divided the genus into the genera *Helicolimax* and *Helicarion*. The last-named sub-genus consists of exotic species, which seemed to him to approximate more nearly to *Parmacella*. We subjoin illustrations to these two genera. [HELICIDÆ; LIMAX.]

Helicolimax pellucida.

Shell magnified. Animal natural size.

a, Shell of *Helicarion Cuvieri*; b, *Helicarion Freycineti*.

VITRIOL, BLUE. [COPPER.]

VITRIOL, GREEN. [IRON; MELANTERITE.]

VITRIOL, WHITE. [ZINC.]

VITTÆ, in Botany, a term most frequently applied to the receptacles of oil which are found in the fruits of Umbelliferous plants. [UMBELLIFERÆ.]

VIVERRA. [VIVERRIDÆ.]

VIVERRIDÆ, a family of Carnivorous Animals, embracing the genus *Viverra* of Linnaeus. This author thus defines his genus *Viverra*:—Dentes primores vi: intermedii brevioribus. Molares plus quam tres. Lingua retrorsum, sæpe aculeata. Ungues exserti.

The species comprised under this genus, in the twelfth edition of the 'Systema Naturæ,' are *Viverra ichneumon*, *V. nasua*, *V. narica*, *V. putorius*, *V. Zibetha*, and *V. Genetta*.

Linnaeus places the genus between *Felis* and *Mustela*.

The Civettes (*Viverra*) of Cuvier are arranged, in his last edition of the 'Règne Animal,' between the Dogs (*Canis*) and the Hyenas, which are immediately followed by the Cats.

The Civets are subdivided into, 1, the Civets, properly so called (*Viverra*, Cuv.); 2, the Genets (*Genetta*, Cuv.); 3, the Paradoxure (*Paradoxurus*, F. Cuv.); 4, the Mangoustes (*Herpestes*, Ill.); 5, the Suricates (*Ryzana*, Ill.); and, 6, the Mangas (*Crossarchus*, F. Cuv.).

Cuvier says of this group that the genera composing it have three false molars above, and four below, the anterior of which sometimes fall out; two rather large tuberculous teeth above, a single one below, and two projecting tubercles on the inside of their lower canine anteriorly, the rest of that tooth being more or less tuberculous. Their tongue he describes as beset with sharp and rough papillæ; their claws are raised more or less in walking; and there is near their anus a more or less deep pouch, where particular glands secrete an unctuous and often odoriferous substance.

The *Viverrina*, Dr. J. E. Gray's third family of *Felidæ*, is the first of his second subdivision of that family, namely, *Necrophaga*.

The *Viverrina* comprise the following genera:—*Viverra*, *Proteles*, NAT. HIST. DIV. VOL. IV.

Prionodon, *Genetta*, *Galidia*, *Galictis*, *Herpestes*, *Mungos*, *Atilax*, *Ichneumia*, *Uva*, *Crossarchus*, *Ryzana*, *Hemigale*, *Paradoxurus*, *Poguma*, *Arctictis*, *Cynogale*, *Cryptoprocta*, and *Bassaria*.

Viverra (Cuv.).—The deep pouch situated between the anus and the sexual organs, is divided into two bags filled with an abundant concretion of the consistence of pomade, exhaling a strong musky odour, secreted by glands which surround the pouch. Pupil of the eye round during the day. Claws only half retractile. Dental Formula:—

$$\text{Incisors, } \frac{6}{6}; \text{ Canines, } \frac{1-1}{1-1}; \text{ Molars, } \frac{6-6}{4-4} = 36.$$

V. Civetta, the Civet. Length of the elongated body from two to three feet; tail about half as long as the body. Height from ten inches to a foot. Hair of the body long, brownish-gray, with numerous interrupted transverse black bands or spots of the same colour. The hairs on the ridge or middle line of the back from between the shoulders are longer, and can be raised or depressed at the pleasure of the animal. Legs and most part of tail black; upper lip and sides of the neck almost white. Eyes surrounded each by a black patch. Two or three black bands pass from the base of the ears obliquely towards the shoulder and neck, which last has a broad black patch. It is a native of the north of Africa.

The Civet approaches in its habits nearest to the Foxes and smaller Cats, preferring to make its predatory excursions against birds and smaller quadrupeds in the night, although, like these *Carnivora*, it will occasionally attack its prey in the daytime.

In a state of captivity it becomes in a degree tame, but never familiar, and is dangerous to handle. The young are fed on farinaceous food, millet-pap for instance, with a little flesh or fish; and, when old, on raw flesh. Many of them are kept in North Africa to obtain the perfume which bears the name of the animal, and brings a high price. The civet is procured by scraping the inside of the pouch with an iron spatula at intervals about twice a week. If the animal is in good condition and a male, especially if he has been irritated, a dram or thereabouts is obtained each time. The quantity collected from the female does not equal that secreted by the male. Civet, like most other articles of this nature, is much adulterated, and it is rare to get it quite pure. The adulteration is effected with suet or oil to make it heavier.

Civet (*Viverra Civetta*).

V. Rasse is a species found in Java. Dr. Horsfield says "it supplies in Java the place which the *V. Civetta* holds in Africa, and the *V. Zibetha* on the Asiatic continent from Arabia to Malabar, and in the large islands of the Indian Archipelago. I have endeavoured to show that, by its form and marks, it is essentially distinct from the *V. Zibetha*; and it differs as much in its natural disposition as in external characters. The *V. Zibetha* is an animal comparatively of a mild disposition; it is often found among the Arabs and Malays who inhabit the maritime parts of Borneo, Macassar, and other islands, in a state of partial domestication; and, by the account of the natives, becomes reconciled to its confinement, and in habits and degree of tameness resembles the common domestic cat. The *Rasse*, on the contrary, preserves in confinement the natural ferocity of its disposition undiminished. As the perfume is greatly valued by the natives, it is frequently kept in cages; but, as far as I have observed, must always be obtained for this purpose from a wild state, never propagating in a state of confinement.

"The *Rasse* is not unfrequently found in Java, in forests of a moderate elevation above the level of the ocean. Here it preys on small birds and animals of every description. It possesses the sanguinary appetite of animals of this family in a high degree, and the structure of its teeth corresponds strictly with the habits and modes of life. In confinement it will devour a mixed diet, and is fed on eggs, fish, flesh, and rice. Salt is reported by the natives to be a poison to it. The odoriferous substance is collected periodically: the animal is placed in a narrow cage, in which the head and anterior extremities are confined; the posterior parts are then easily secured, while the civet is removed by a simple spatula."

The substance obtained from the *Rasse* agrees with the civet afforded by the *V. Civetta* and *V. Zibetha* in colour, consistence, and odour. It is a very favourite perfume among the Javanese, and applied

both to their dresses and, by means of various unguents and mixtures of flowers, to their persons. Even the apartments and the furniture of the natives of rank are generally scented with it to such a degree as to be offensive to Europeans; and at their feasts and public processions the air is widely filled with this odour. ('Zoological Researches.')

Rasse (*Viverra Rasse*). (Horsfield.)

Genetta, Cuv.—Odoriferous pouches reduced to a slight depression formed by the projection of the glands, and without any perceptible excretion, although the odour is manifest. The pupil has a vertical slit, and the claws are entirely retractile, as in the Cats.

G. vulgaris, the Common Genet (*Viverra Genetta*, Linn.), is gray, spotted with small black or brown patches, which are sometimes round and sometimes oblong; the tail, which is as long as the body, is ringed with black and white, the black rings being to the number of nine or eleven. There are white spots on the eyebrow, the cheek, and on each side of the end of the nose. It is found from the south of France to the Cape of Good Hope, and Cuvier says that it differs in the size and number of the patches, the bands along the shoulder and neck, the lines on the nape, &c.

The Genet loves lowlands, particularly the banks of rivers and the neighbourhood of springs. In Constantinople it is domesticated, and kept in the houses, where it is said to catch mice as well as a cat.

Common Genet (*Genetta vulgaris*).

Paradoxurus (F. Cuv.).—Has the character generally of the Civets and Genets. Tail capable of being rolled from above downwards to its base, but not prehensile. Toes five, nearly palmated; sole of the foot tuberculous, applied throughout its surface to the ground; claws semi-retractile. Eyes with the pupil slit longitudinally. No pouch.

Dental Formula:—Incisors, $\frac{6}{6}$; Canines, $\frac{1-1}{1-1}$; Molars, $\frac{6-6}{6-6}$ = 40.

P. typus, the Paradoxure. It was confounded by Buffon with the Common Genet, a confusion which M. F. Cuvier dissipated; in form and habits, indeed, it does not differ much, and the toes and claws closely agree in number and retractility. The secretory pouch is absent. The tail is very peculiar: as long as the body, and depressed, not to say flattened, above and below; the extreme or more distant half is, when extended, turned over, so that the lower side is upper-

most, and the animal can roll it up spirally from above, downwards and from the extremity to the base.

Paradoxure (*Paradoxurus typus*). (F. Cuvier.)

Mangusta, Olivier. [ICHNEUMON.]

M. Javanica, has the ear hearing considerable resemblance to that of man. Pouch very extensive. Hair long on the body and tail, but short on the head and extremities, rigid and glossy. Length, including the tail, about 2½ feet.

Rumphius gives a curious account of this species, which is the Garangan of the natives, who greatly admire its agility. It attacks and kills serpents with the greatest boldness; and Rumphius speaks of its value in performing this service and its method of encountering those reptiles. The Javanese nobles, he says, pay a considerable price for it, that they may amuse themselves with the sport of these fights. When the two enemies are opposed to each other, the serpent endeavours to twine round the quadruped and kill it. The latter submits to this, but inflates itself to turgescence; and when the serpent enfolds it and advances its head to give the deadly bite, the Mangouste contracts his body, slips out of the folds, seizes the serpent by the neck and kills it.

Garangan (*Mangusta Javanica*). (Horsfield.)

Dr. Horsfield states that the *Mangusta Javanica* is found most abundant in the large teak-forests, and that it is very expert in burrowing in the ground in pursuit of rats. "It possesses," says our author in continuation, "great natural sagacity; and from the peculiarities of its character, it willingly seeks the protection of man. It is readily tamed, and in a domestic state it is docile and attached to its master, whom it follows like a dog; it is fond of caresses, and frequently places itself erect on its hind legs, regarding everything that passes with great attention. It is of a very restless disposition, and always carries its food to the most retired place in which it is kept to consume it. It is very cleanly in its habits. It is exclusively carnivorous, and very destructive to poultry, employing great artifice in the surprising of chickens. For this reason it is rarely found in a domestic state among the natives, as one of their principal articles of food is the common fowl, and great quantities are reared in all the villages. The Javanese also, like the Mohammedans in general, have a great partiality for cats, and they are unwilling in most cases to be deprived of their society for the purpose of introducing the Garangan. It has also been observed that its sanguinary character shows itself occasionally in a manner that renders it dangerous in a family as a domestic animal, and it indulges at intervals in fits of excessive violence."

Ryzana, Ill.—Feet rather long; toes four, armed with robust but not retractile claws proper for hurrowing. Tongue furnished with horny papillæ. Ears small. Pouch leading into the anus. Tail long, slender, and pointed.

Dental Formula :—Incisors, $\frac{6}{6}$; Canines, $\frac{1-1}{1-1}$; Molars, $\frac{5-5}{5-5}$ = 36.

Teeth of *Ryzana*. (F. Cuvier.)

This genus resembles the *Ichneumons* in the tinting and stripes of the coat; but the legs are longer, and there are only four toes on each foot. The dentition too differs, for they are without the small molar immediately behind the canine.

R. Capensis, the Suricate, is about four feet long, including the tail. Fur a mixture of brown, white, yellowish, and black. The colour of the hair is brown at the bottom, black near the tips, and hoary at the points; those on the back undulated; inside of the legs yellowish-brown; tail tufted with black. It is found in Africa, and the Cape of Good Hope.

At the Cape, Pennant states that this species is called Meer-Rat. In habits and manner it is said to resemble the *Mangoustes*, and its urine is very fetid. It feeds on flesh, preys on mice, and is a great enemy to *Blattæ*.

Suricate (*Ryzana Capensis*).

Crossarchus, F. Cuv.—Head more rounded than that of the *Ichneumons*, and the muzzle larger. The pupil round. The muzzle moveable. The ears small, round, and bilobate. The tongue smooth on its edges, but papillose and horny at the centre. The tail flattened. Five toes on each foot. Pouch secreting an unctuous fetid matter.

C. obscurus is nearly two feet long, including the tail, which is about eight inches. Fur consisting of two kinds of hair; the external rather

harsh and of a uniform brown, a little brighter on the head, cheeks pale. It is a native of the coast of Africa and Sierra-Leoue. It feeds on flesh, and is cleanly and well-behaved in confinement.

Crossarchus obscurus.

Cryptoprocta, Bennett.—This genus approaches more nearly than most of the other forms of this family to the *Felidae*, having the claws on both feet truly retractile, and furnished with the retractile ligaments; those of the anterior limbs being also acute, both at their points and edges.

Body slender, limbs robust and of moderate length; head narrow and slightly elongated; glandular muzzle small; nostrils with a deep lateral sinus; whiskers numerous and stiff, the longest exceeding the head in length; eyes rather small, placed above the angle of the mouth, the opening of which is not much prolonged backwards; ears unusually large, rounded, with a fold on the posterior margin and one or two sinuosities within, hairy both within and without, except in the auditory passage; neck slender; anterior limbs somewhat shorter than the posterior; tail (which appeared to be mutilated at the extremity) as long as the body, reaching, when retroverted, to between the ears, cylindrical, and uniformly hairy; soles of anterior feet naked to the whole extent of the carpus; of the posterior, nearly to the heel: claws retractile, five on each foot; on the anterior, sharp-pointed and edged, compressed, curved, short, and cat-like; on the posterior, rather larger, compressed, less curved, and obtuse. The toes united nearly to the tips; on the fore feet the middle the longest; those on each side scarcely shorter and nearly equal to each other; innermost and outermost also nearly equal to each other, but still shorter than the adjoining ones: on the posterior feet, third and fourth toes nearly equal and rather longer than the second and fifth; thumb considerably shorter.

C. ferox is a native of Madagascar.

Cryptoprocta ferox.

Nasua, Storr.—Feet pentadactyle, furnished with sharp claws. Tail long, pointed, not prehensile. Nose very much elongated, and very moveable. No anal follicles. Six ventral teats.

Dental Formula :—Incisors, $\frac{6}{6}$; Canines, $\frac{1-1}{1-1}$; Molars, $\frac{6-6}{6-6}$ = 40.

N. narica, the Brown Coati Mondí. It is a native of America.

Brown Coati (*Nasua narica*).

Cercoleptes caudivolvus, the Potto, or Kinkajou, is referred by some writers to *Ursida*, but by others to the *Viverridæ*. It has the following dental formula:—

$$\text{Incisors, } \frac{6}{6}; \text{ Canines, } \frac{1-1}{1-1}; \text{ Molars, } \frac{5-5}{5-5} = 36.$$

Teeth of Potto or Kinkajou, twice the natural size. (F. Cuvier.)

Specimens of this animal are to be seen alive in the gardens of the Zoological Society, Regent's Park.

Potto or Kinkajou (*Cercoleptes caudivolvus*). (F. Cuvier.)

VIVIANACEÆ, *Vivianads*, a natural order of Exogenous Plants with free stamens, no disc, albuminous seeds, a curved embryo, permanent petals, and a ribbed calyx. The species are herbaceous or half-shrubby plants, with opposite or whorled leaves, without stipules. They are related to *Tiliaceæ* and *Tropæolaceæ*. All the species inhabit Chili and South Brazil. There are four genera and fifteen species.

(Lindley, *Vegetable Kingdom*.)

VIVIANITE. [IRON.]

VIZACHA. [CHINCHILLIDÆ.]

VOANDZEIA, a Plant belonging to the natural order *Leguminosæ*. It was formerly called *Glycine subterranea*. It is allied to *Arachis hypogæa*, or the Earth-Nut of the coast of Africa and of Asia. The only species of the genus is *V. subterranea*, which is so called in consequence of its peduncles bending down and sinking into the ground, where the pods ripen.

VOCHYA'CEÆ, or **VOCHYSIA'CEÆ**, *Vochyads*, a natural order of Exogenous Plants. The species belonging to this order are trees, with opposite branches, which, when young, are 4-cornered. The leaves are entire, mostly opposite, sometimes towards the extremities of the branches they are alternate, and are supplied with two stipules at their base. The flowers are symmetrical and partially complete, the calyx is imbricated, ovules ascending, and stigmas single. The affinities of this order are with *Sapindaceæ*, *Staphyleaceæ*, and *Celastraceæ*.

There are about 40 species of this family altogether; they are all natives of equinoctial America, where they are found inhabiting ancient forests, the banks of streams, and sometimes the sides of mountains to a very considerable elevation. None of these trees are remarkable for their beauty or for their uses, but the striking irregularity of the structure of their flowers renders them objects of great interest to the botanist.

VOICE. [LARYNX.]

VOLATILE OILS. [OILS.]

VOLBORTHITE, *Vauadiane* of Copper, is a Mineral occurring in small clusters of olive-coloured crystals, sometimes united into globular masses. Streak green, almost yellow. In thin splinters transparent, with a vitreous lustre. Hardness, scratches calc spar. Specific gravity 3.55. It was found by Von Volborth on examining some Siberian copper-ores.

VOLKONSKOITE, a Mineral containing oxide of chromium. It occurs amorphous. Fracture conchoidal or uneven. Very soft; feels smooth. Colour fine grass-green. Dull; assumes a polish when rubbed by the fingers. When heated in a glass tube, loses water, and becomes of a brown-colour; by calcination loses about one-third of its weight, and becomes of a dark brown-colour.

It was found in Mount Jessenitski, in the government of Perm, Siberia, occurring in thin veins and nests. It contains silica, green oxide of chromium, peroxide of iron, magnesia, and water.

VOLTAITE, *Iron Alum*, a Mineral occurring crystallised in regular octohedrons. Colour brown or black. It is found at the Solfatara near Naples, and consists of sulphuric acid, protoxide of iron, alumina, potash, and water.

VOLTZIA, a genus of Fossil Plants.

VOLTZITE. [ZINC.]

VOLUTA. [VOLUTIDÆ.]

VOLUTELLA. [VOLUTIDÆ.]

VOLUTIDÆ, a family of Gasteropodous *Mollusca*, whose shells are prized by collectors above most others for their beauty and rarity; and which, from their numbers and carnivorous habits, are

powerful agents in keeping to her *Mollusca* and *Conchifera* within due limits.

The genus *Voluta* stands, in the last edition of the 'Systema Nature,' revised by Linnæus, between the genera *Bulla* and *Buccinum*, with the following definition:—Animal, a Limax, or Slug. Shell unilocular, spiral. Aperture ecaudate, subeffuse. Columella or pillar plaited. No labium nor umbilicus.

Linnæus thus subdivides the genus:—

* Aperture entire.

Species:—*V. Auris Mide*, *Auris Judæ*, *tornatilis*, *solidula*, *livida*, and *coffa*.

** Cylindroid (subcylindrical and emarginate).

Species:—*V. porphyria*, *oliva*, and *ispidula*.

*** Ovate (obovate, effuse, emarginate).

Species:—*V. dactylus*, *miliaria*, *monilis*, *persicula*, *pallida*, *faba*, *glabella*, *reticulata*, *mercatoria*, *rustica*, *paupercula*, *mendicaria*, and *cancellata*.

**** Fusiform.

Species:—*V. tringa*, *corniculata*, *virgo*, *scabricula*, *rufina*, *sanguisuga*, *caffa*, *morio*, *vulpecula*, *plicaria*, *pertusa*, *mitra*, *musica*, *vespertilio*, *ebraea*, *turbinellus*, *capitellum*, *ceramica*, *pyrum*, and *lapponica*.

***** Ventricose.

Species:—*V. Æthiopica*, *cymbium*, and *olla*.

The species belonging to the Linnæan genus *Voluta*, when Lamarck published his 'Animaux sans Vertèbres,' amounted to nearly 300, and they would be now considerably above that number. Some of these species are even referred to other families.

The following is a definition of the *Volutidæ* as at present constituted:—Shell turreted or convolute; aperture notched in front; columella obliquely plaited; operculum absent. Animal with a recurved siphon; foot very large, partly biding the shell; mantle often lobed and reflected over the shell; eyes on the tentacles or near their base; lingual ribbon linear; rachis toothed; pleura unarmed.

We give the genera of this family and illustrations of some of the species:—

Voluta has the shell ventricose, thick; spire short, apex mamillated; aperture large, deeply notched in front; columella with several plaits. *V. musica* and a few others have a small operculum. Animal, eyes on lobes at the base of the tentacles; siphon with a lobe on each side, at its base; lingual teeth 3-cusped.

This comprises *Cymbiola* and *Harpula* of Sowerby, *Volutella* of D'Orbigny, *Scapha* of Gray. *Volutulites* and *Scaphella* of Sowerby, and *Melo* of Broderip are sub-genera. Seventy recent species and eighty fossil species are known.

V. undulata has the shell ovate-fusiform, smooth, yellowish-white, clouded with fulvous or purple-black spots, ornamented with numerous bay or brown longitudinal undulatingly flexuous lines; principal plaits on the pillar four; sometimes two smaller additional ones.

It is found on the coasts of Australia, Port Western, Bass's Strait, the Island Maria, &c.

Voluta undulata. (Animal and Shell.)

Anterior part seen from above.

Voluta undulata. (Animal and Shell.)

The whole seen from below. ('Astrolabe.')

Shell of *Voluta undulata*, showing the plaits on the pillar.

V. pacifica has the shell ovate-fusiform, anteriorly tuberculiferous

Voluta pacifica. ('Astrolabe.')

pale yellow or flesh-colour ornamented with brown spotted bands, and bay vein-like markings; pillar 5-plaited.

It is found in New Zealand, in the Bay of Islands.

V. (Melo, Broderip) Æthiopicus has the shell obovate, ventricose, of an orange-cinnamon colour, the spire coronetted with thick-set short-vaunted spines; pillar 4-plaited.

This shell is a native of the African Ocean and the East Indian seas.

Animal of *Voluta (Melo) Æthiopicus*. ('Uranie,')

Shell of *Melo*. Back and front view.

V. resperitilio has the shell turblated, armed with strong distant acute tubercles, white, yellowish, or reddish, painted with angularly flexuous spots; spire muricated, the apex with small tubercles; lip with a sinus above; pillar 4-plaited.

It is found in the Indian Seas, Amboyna, Moluccas, &c.

The species of *Voluta* have been found at depths ranging from 7 to 14 fathoms. The species are very numerous and very beautiful.

Voluta resperitilio. ('Astrolabe,')

Mitra, *Mitre* Shells, have the shell fusiform, thick; spire elevated, acute; aperture small, notched in front; columella obliquely plaited; operculum very small.

The animal has a very long proboscis; it emits a purple liquid, having a nauseous odour, when irritated. The eyes are placed on the tentacles, or at their base. Three hundred and fifty recent species and ninety fossil have been described.

M. episcopalis, Bishop's Mitre Shell. The animal has a narrow foot, compressed and channelled at its root, nearly square and slightly auriculated in front with a marginal furrow, and pointed behind. The head is very small, rounded, with two tentacles, which are scarcely a line and a half in length; the eyes sessile at their base. An enormous proboscis, which is sometimes double the length of the shell.

The respiratory siphon does not project beyond the canal; it is marked with black at the point: the rest of the animal is yellowish. The proboscis is white.

Mitra episcopalis, seen from below, with its long proboscis. ('Astrolabe,')

Shell of *Mitra episcopalis*, showing the plaits on the pillar.

Shell turreted, smooth, white, spotted with bright red; pillar four-plaited; outer lip denticulated at its lower part; epidermis thin. It is found in East Indian seas and islands of the South Sea, Tongataboo.

M. adusta, has the shell fusiform, turreted, albido-lutescent, ornamented with longitudinal rufous-brown spots; the striae transverse, impressed, rather remote, and dotted; the sutures crenulate; the pillar five-plaited. It is found at Timor, Vanikoro.

There are at least two varieties.

Mitra adusta, seen from below. ('Astrolabe.')

M. corrugata. The shell is ovate-fusiform, longitudinally plicated, transversely rugous, whitish; bands and belts brown; whorls angulated above; the last whorls with a submucated angle; pillar four-plaited. It is found in the Indian Ocean and New Guinea.

Mitra corrugata. ('Astrolabe.')

The species have been found at depths varying from the surface to seventeen fathoms, on reefs, sandy mud, and sands. The species are all inhabitants of warm countries.

Imbricaria and *Cylindra* are sub-genera of *Mitra*.

Volvaria has the shell cylindrical, convolute; spire minute; aperture long and narrow; columella with 3 oblique plaits in front. The species, five in number, are all fossil.

Marginella has the shell smooth, bright; spire short or concealed; aperture truncated in front; columella plaited; outer lip (of adult) with a thickened margin. Animal similar to *Cypræa*.

Oliva, which is sometimes referred to *Buccinidae*, has the following characters:—Animal involved, compressed, with a small head terminated by a proboscis; tentacles approximated, enlarged at their base and subulate at their extremity, carrying the eyes on small convexities about their middle part externally; foot very large, oblong, and slit transversely anteriorly; mantle with a single lateral lobe covering the shell in great part, with two tongue-like processes at the side of the branchial opening, and forming in front a very elongated siphon; a single branchial pectination; male organ very voluminous, on the anterior part of the right side. Operculum horny, elongated, very small, with a marginal apex.

Oliva textilina. ('Astrolabe.')

M. Rang, whose descriptions we have selected, states that the genus *Oliva* is one of the richest in the colour and brilliancy of the shell and variety of species; and he refers to the beautiful collection of *M. Duclos*, who had made the genus his particular study.

O. textilina has the shell cinereous white, subreticulated with flexuous dotted lines, with two brown bands inscribed as it were with characters; the callus of the canal prominent. It is found in the Antilles and New Guinea.

O. maura has the shell cylindrical, the apex retuse, black; lip sub-plicate externally; aperture white. It is found in the East Indian Ocean, Australia, and Amboyna.

Oliva maura. ('Astrolabe.')

O. sanguinolenta, has the shell cylindrical, very delicately reticulated, with rufous brown small lines, girt with two brown zones; the pillar orange-red. It is found in the East Indian Ocean and on the coast of Timor.

Oliva sanguinolenta. ('Astrolabe.')

a, Shell seen from below; b, animal out of the shell, shown as when creeping on its large foot.

The species have been found at depths varying from the surface to twelve fathoms, on mud, saudy-mud, coarse sand, &c. The species are foud of flesh, but they only suck the juices; and at Mauritius they are taken with that bait in the following manner, according to Lieutenant Harford, who was for some time there, brought home some very fine Mauritian shells, and gave the information to Mr. Broderip. The fishery was carried on by means of a line made to run parallel with the bottom of the sea, to which line small nooses, each containing a piece of the arms of a cuttle-fish (*Sepia*), were appended so that the bait touched the bottom. To one end of the line a chain-shot was attached by way of mooring; and over it were a buoy and a flag. The other end of the line swung with the tide, and that end was also marked by a buoy and a small flag. The sport was carried on in deep water over sand-banks, and the best times were the morning and the evening. The apparatus was occasionally cautiously drawn up and the Olives which were found adhering to the bait were taken into the boat in which the fishermen were.

Olivella and *Scaphula*, Sowerby, and *Agaroma*, Gray, are sub-genera; 117 fossil and 20 recent species have been described. (Woodward, 'Manual of the Mollusca.')

Cymba, Broderip. The species are called Boat-Shells. The shell is like *Volva*; nucleus large and globular; whorls few, angular, forming a flat ledge round the nucleus. The foot of the animal is very large, and deposits a thin enamel over the under side of the shell. It is ovoviparous, and the young animal is very large when born; the nucleus becomes partly concealed by the growth of the shell. Ten recent species have been described.

C. Neptuni has the shell obovate, tumid, ventricose, of a brownish-red, covered with a strong brown epidermis, over which an enamel-like glaze is extended from the pillar over about a fourth part of the shell, leaving the epidermis of the back uncoated. In full-grown specimens the spire and apex are entirely concealed, and the upper border of the

body-whorl, which is carinated and somewhat reflected, overhangs both, so as to form an open somewhat rounded concavity. Pillar 4-plaited. It is found on the African coasts in shallow water on sands and mud.

Cymba Neptuni.

a, seen from below, showing the plaits of the pillar; *b*, seen from above; *c*, young seen from above.

VOLUTILITHES (Fossil). [Volutidæ.]

VOLVA, in Botany, is the external membranous or fleshy covering which incloses the stipes and pileus of the young state of many of the order *Fungi*.

VOLVARIA. [Volutidæ.]

VOLVOX, a genus of organic beings referred by Ehrenberg to his family of *Infusoria*. Siebold was the first to doubt the correctness of Ehrenberg's classification, and the result has been that through the

subsequent researches of Williamson, Busk, and Cohn, the species of *Volvox* are now regarded as forms of the vegetable kingdom.

Ehrenberg describes three species of *Volvox*: *V. globator*, *V. aureus*, and *V. stellatus*. A fourth form is described by Ehrenberg under the name of *Sphaerosira Volvox*.

The following is Mr. Busk's account of these forms of *Volvox*:—

"The more common and best known form of *Volvox globator*, to the naked eye, or under a low power, appears as a transparent sphere, the surface of which is studded with numerous regularly placed green granules or particles, and which contains in the interior several green globules, of various sizes in different individuals, though nearly always of uniform size in one and the same parent globe.

"These internal globes, which are the young or embryo *Volvox*, at first adhere to the wall of the parent cell, although the precise mode of connection is not very apparent. When thus affixed, they are in a different concentric plane to the smaller green granules. At a later period, and after they have attained a certain degree of development, these internal globes become detached, and frequently exhibit a rotatory motion, similar to that of the parent globe.

"In the form of *Volvox*, termed *V. aureus* by Ehrenberg, the outer sphere, or cell, exhibits precisely the same structure as the above, the only apparent difference between them consisting in the deeper green colour of the internal globules. These however soon exhibit a more important distinctive character in the formation of a distinct cell-wall of considerable thickness around the dark-green globular mass. This wall becomes more and more distinct; and, after a time, the contents, from dark-green, change into a deep orange-yellow; and simultaneously with this change of colour the wall of the globule acquires increased thickness, and appears double.

"The third form, or *Volvox stellatus*, differs in no respect from the two former, except in the form of the internal globules, which exhibit a stellate aspect, caused by the projection on their surface of numerous conical eminences, formed of the hyaline substance of which the outer wall of the globule is constituted. The deep green colour of the contents of these stellate embryos, and their subsequent changes into an orange colour, at once point out their close analogy with those of *V. aureus*. I have no doubt of their being merely modifications of the latter: and in fact the two forms are very frequently to be met with intermixed, and on several occasions I have observed smooth and stellate globules in the interior of one and the same parent globe.

"The organism described and figured by Ehrenberg, under the name of *Sphaerosira Volvox*, also presents the appearance of a transparent globe set with green spots, but it differs from the foregoing in two important respects:

"1. In the absence of any internal globules or embryos.

"2. In the irregular size of the green granules lining the wall, which, instead of being of a uniform size, are of various dimensions."

Mr. Busk and Professor Williamson, in the first volume of the new series of the 'Microscopical Society's Transactions,' have furnished in great detail an account of the development of these curiously organised granules. From their observations, it appears that the green ciliated granules which stud the surface of the *Volvox* are produced from a central embryonic mass of protoplasm by successive division by segmentation. Mr. Busk observed in these green granules a curious phenomenon.

"It will also be observed, that each ciliated cell or zoospore, as it may analogically be termed, contains a green granular mass or masses, composed, for the most part probably, of chlorophyll granules and a more transparent body, which I suppose may be regarded as a nucleus, and derived, as it would appear, from one of the bright sporules which have been noticed before. At an early period after the maturity or completion of the zoospores they exhibit a minute circular clear space, or sometimes, but I think rarely, more than one, which is worthy of very attentive consideration. This space is of pretty uniform size in all cases, and about 1/9000th of an inch in diameter. It may be situated in any part of the zoospore, or not unfrequently in the base, or even in the midst of one or other of the bands of protoplasm connecting it with its neighbours. Its most important character consists in its contractility—a property already known to be possessed by similar spaces or vacuoles in vegetable spores; but what appears to me a very curious, and as yet unnoticed, peculiarity of this contraction, consists in the fact that it is very regularly rhythmical. In several cases in which I have watched the phenomenon in question, uninterruptedly, for some time, the contractions or pulsations occurred very regularly at intervals of about 38" to 41". In one case however, if I was not misled in the observation, the interval was about twice this, namely, 1' 25". The contraction, which appears to amount to complete obliteration of the cavity of the vacuole, takes place rapidly or suddenly, as it were, whilst the dilatation is slow and gradual." This contraction of vacuolar spores has since been observed by Cohn in a species of *Protophycus*.

Mr. Busk thus sums up the result of his observations upon *Volvox globator*:—

"1. That it originates in an apparently nucleated discoid cell, which is generated in the interior of the parent, and liberated in a perfect though not fully matured form, within which are contained similar germs.

"2. That the contents of this apparently nucleated discoid cell,

consisting of a grumous material and refractive amylaceous (?) spherules, after a time undergo segmentation, at the same time exhibiting a distinct wall, beyond which is a delicate areola, apparently of a gelatinous consistence.

"3. That this segmentation, attended with a corresponding augmentation in the number of the refractive spherules, terminates ultimately in the formation of numerous contiguous particles or segments.

"4. That these ultimate segments are gradually separated from each other, remaining connected only by elongated processes or filaments, and constituting the ciliated zoospores of the mature *Volvox*.

"5. That these zoospores at first are simple masses of protoplasm, containing a transparent nuclear body, and that afterwards they present for a time clear circular spaces, which contract rhythmically at regular intervals; and are subsequently furnished with a brown eye-spot; and at a very early period with two long retractile cilia, which arising from an elongated hyaline beak penetrate the parent cell-wall, and exert active movements external to it.

"6. That in a concentric plane internal to these ciliated zoospores are placed the germs of future individuals destined to follow the same course."

VOMER. [SKELETON.]

VULPES, Brisson, the generic name for a species of that subdivision of the great genus *Canis*, which has the pupils of the eyes elliptical or almost linear by day, though they become round or nearly so in the hours of darkness.

Although the dental formula and general osteological character of the Foxes agree with that of the true Dogs, the lengthened and sharp-pointed muzzle, the round head, the erect and triangular ears, the form of the pupil, the long body, short limbs, and elongated, thick, and bushy hush, constitute differences which separate the former from the latter, at least sub-generically.

V. vulgaris (Brisson), the Common Fox; *Canis vulpes*, and *C. alopex* (the latter the variety, if variety it may be called, with the tip of the tail black) of Linnaeus; Volpe of the Italians; Raposa of the Spanish; Rapoza of the Portuguese; Fuchs of the Germans; Vos of the Dutch; Raff of the Swedes; Rev of the Danes; Tod of the Scotch; Llwynog, fœm. Llwynoges of the Welsh, is too well known to require description. The time of gestation may be taken at from 60 to 65 days, and the birth of the young takes place in April. In a year and a half they attain their full size, and have been known to live 13 or 14 years; but as this can only have been ascertained, observes Mr. Bell, of individuals in confinement, it is very probable that, in a state of nature, it considerably exceeds that period. Of its cunning much has been said, and a great deal of it is true. The reader will find some interesting remarks on the habits and economy of the Common Fox by Dr. Weissenborn in the number of Loudon's 'Magazine' (N. S.) for October 1837.

The Common Fox inhabits, according to Linnaeus, Europe, Asia, and Africa. Cuvier mentions it as reaching from Sweden to Egypt, both inclusive. Mr. Strickland notes it as occurring near Smyrna. The Fox named *Melanogaster* by the Prince Bonaparte in his 'Fauna Italica' is probably a variety only. The strong smell proceeding from the anal glands and urine of the Common Fox is very offensive.

V. fulvus, the American Fox, which is, according to Sir John Richardson, very plentiful in the wooded districts of the Fur Countries, about 8000 (skins) being annually imported into England from thence, bears a strong resemblance to the Common European Fox, and, until De Beauvois pointed out its peculiarities, was considered identical with it. Thus it is the European Fox of Pennant. Sir John Richardson observes that the American, or Red Fox, does not possess the wind of its English congener, its strength being exhausted by the first short burst, though it runs about a hundred yards with great swiftness, and is soon overtaken by a wolf or a mounted huntsman. He gives the following synonyms:—European Fox of Pennant; Red, or Large Fox, of Hutchins; Large Red Fox of the Plains of Lewis and Clark; Renard de Virginie of Palisot de Beauvois; *Canis fulvus* of Deamarest; Red Fox of Sahine (Franklin's 'Journ.'), and Mak-keeshew of the Cree Indians.

V. lagopus, the Arctic Fox, is considered by Sir John Richardson to be identical with the Pied Foxes of James; *Canis lagopus* of Linnaeus and Forster, Colonel Sabine, Mr. Sabine, Dr. Richardson, and Dr. Harlan; Arctic Fox of Pennant and Hearne; Greenland Dog of Pennant (?), a young individual; Isatis and Arctic Fox of Godman; Stone Fox of authors; Terreanec-arioo of the Esquimaux of Melville Peninsula; Terieniak of the Greenlanders; Wappeeskee-shew-mak-keeshew of the Cree Indians; and Peszi of the Russians.

This creature is extremely cleanly. It never soils its habitation, nor has it any unpleasant smell. It breeds on the sea-coast, chiefly within the Arctic Circle; is very unuspicious and easily taken by traps, even, as it is stated, when baited in its presence. Captain Lyon, R.N., received fifteen from one trap in four hours. It is gregarious, forming burrows in sandy spots, 20 or 30 together. Sir John Richardson saw one of these fox villages on Point Turnagain, in 68½° N. lat. It soon becomes tame in confinement and is eager to hide its food as soon as it obtains it, even when there seems no danger of losing it. Snow is the material generally used for this purpose, and when piled over the food is forcibly pressed down by the nose.

NAT. HIST. DIV. VOL. IV.

"This Fox is found in the highest northern latitudes throughout the winter. The young generally migrate to the southward late in the autumn and collect in vast multitudes on the shores of Hudson's Bay: they return early the following spring along the sea-coast to the northward, and seldom again leave the spot they select as a breeding-place." (Captain James Ross.) "Their southern limit in North America appears to be about 50° N. lat. They are numerous on the shores of Hudson's Bay, north of Churchill, and are found at Behring's Straits; but the brown variety (*V. fuliginosus*) is the more common in the latter quarter." (Sir John Richardson.)

The fur is considered to be of small value in commerce, but the flesh is said to be good food, particularly when young. Captain Franklin and his party compared the flavour of the young animal to that of the American hare. In the Arctic voyages they have always been regarded as luxuries.

Arctic Fox (*Vulpes lagopus*) in its winter dress.

Zoologists generally agree that the Sooty Fox, or Blue Fox (*Canis fuliginosus*), is only a variety of the animal above described and figured.

V. caama, the Caama, the smallest of the South African foxes. Dr. Smith, in his 'Catalogue to the South African Museum,' from a specimen in which our figure is taken, observes, that some few individuals are to be met with within the limits of the colony, but that the favourite residence of the species seems to be to the northward; though there it is daily becoming less and less numerous, owing to the skins being much in request among the natives as a covering in the cold season. Many of the Bechnanas, it is stated, find their sole employment in hunting these animals with dogs, or snaring them. Like other foxes, it is a great enemy to birds which lay their eggs on the ground; and it is suspiciously watched by the ostrich in particular during the laying season. The Caama, when he succeeds in obtaining the eggs, pushes them forcibly along the ground till they come in contact with some substance hard enough to break them, when he feasts on the contents. The natives take advantage of the watching of the ostrich for this robber to lure the bird to its destruction. Knowing that the anxious parent runs to the nest the moment a fox appears, they fasten a dog near it and hide themselves.

Caama (*Canis caama*).

The ostrich approaches to drive away the supposed fox, and is shot by the concealed hunter. ('Catalogue of the South African Museum.')

V. Bengalensis (Shaw) is brown above, with a longitudinal black band. The space round the eyes is white, and the tail is terminated with black. It is the Fox of the Dukhun (Deccan), Kokree of the Mahrattas, *Canis Kokree* of Sykes, which the Colonel considers to be new to science, although it much resembles the description of the Corsac, and is described by him ('Zool. Proc.,' 1831) as a very pretty animal, but much smaller than the European Fox.

The *Canis Himalaicus*, Hill Fox of the Europeans in the Doon, in Kumaon, and the more western and elevated parts of the mountains, agrees with the common European and American foxes (*C. vulpes* and *C. fulvus*) in the black marks on the backs of the ears, and in front of the hind and fore legs. The coat consists of long, close, rich fur, as fine as that of any of the American varieties, and of infinitely more brilliant and varied colours. (Royle, 'Flora Himalaica.')

V. Zaarensis, the Fennec. This animal, which has given rise to much controversy, is generally placed by the French zoologists among the Foxes; but the observations of Mr. Yarrell lead him to pronounce decidedly that the Fennec appears to him to belong to the genus *Canis* properly so called; the osteological part of the structure closely resembling that of the dog, and the pupil of the eye being circular.

The Fennec obtained by Bruce when he was consul-general at Algiers, was said to be more frequently found in the territories of Beni Mezzah and Werglab, where the date grows. In these districts the Fennecs are hunted for their skins, for which there is a market at Mecca, whence they are exported to India. Bruce, after leaving Algiers, bought two more Fennecs, one at Tunis, which had been brought by the Fezzan caravan to the Island of Gerba, and thence to the place where Bruce procured it; the other at Senaar, and he knew not whence this last came. Both these resembled the first, and were called Fennecs. The Fennec which Bruce had at Algiers lived for several months, and when he left that place he gave the animal to Captain Cleveland, R.N., who presented it to Mr. Brauder, the Swedish consul. His favourite food consisted of dates or any sweet fruit; but he was also very fond of eggs. He would eat bread when hungry, more especially if it was rendered palatable by honey or sugar. The sight of a bird aroused him to eager watchfulness as long as it was present; and a cat was his aversion. He would endeavour to hide from the latter; but never showed a disposition to resist or defend himself. The animal was disposed to sleep by day, but as night came on it became restless to excess. Bruce never heard it utter any sound. He says that the animal is described in many Arabian books under the name of El Fennec, by which appellation he states that it is known all over Africa; and he conceives that the word is derived from the Greek *φοινίς*, a palm or date-tree, adding that the animal builds his nest on trees, and does not burrow in the earth.

M. Rüppell has figured and described in his 'Atlas Zu der Reise im Nördlichen Afrika,' together with six other species of *Canis*, the Fennec, *Canis Zerda*, Zimm. Three specimens were transmitted to Frankfurt, all perfectly alike in markings, and differing little from each other in size. They were found in the neighbourhood of Amlenkul, and in the desert of Korti, where they inhabit holes made by themselves. They do not nestle on trees, as Bruce asserted.

Fennec (*Vulpes Zaarensis*).

The following species of *Vulpes* are given in the 'List of the Specimens of Mammalia in the British Museum':—*V. vulgaris*, the Fox; *V. aurescens*, the Persian Fox; *V. azarce*, the Agouarachay; *V. Niloticus*, the Sabara; *V. Lagopus*, the Arctic Fox, or Pezöl; *V. cinereo-argenteus*, the Kit-Fox; *V. fulvus*, the American Fox, or Makkeeshew; *V. Bengalensis*, the Kokree; *V. Magellanicus*, the Culpeo; *V. Corsac*,

the Corsac; *V. Caama*, the Asse; *V. dorsalis*, the Senegal Fox; and *V. Zaarensis*, the Fennec.

VULPINITE, a siliceous variety of the Anhydrous Sulphate of Lime. [ANHYDRITE.] It contains about 8 per cent. of silica, and is a little above the usual hardness of anhydrite (3·5).

VULSELLA. [MALLEACEA.]

VULTUR, VULTURE. [VULTURIDÆ.]

VULTURIDÆ, a family of Raptorial Birds, whose geographical distribution is confined to warm climates, where they act as scavengers to purify the earth from the putrid carcasses with which it would otherwise be encumbered.

It has been matter of dispute whether they are directed to their fetid food, for they seldom prey on living animals, by the eye or by the nasal organ. There can however, in our opinion, be little doubt that both the senses are made to contribute to the discovery of the carcass. The lofty flight and telescopic eye are well adapted to detect any dying or dead animal, and as the action of one vulture may be, in all probability is, watched by another, a sort of telegraphic communication as to the position of the object is kept up. [BIRDS; CONDOR.]

The genus *Vultur* of Linnæus stands first in his first order, *Accipitres*, and consists of the following species:—*V. gryphus*, *V. harpyja*, *V. papa*, *V. monachus*, *V. aura*, *V. barbatus*, *V. percnopterus*, and *V. albicilla*. ('Syst. Nat.,' ed. 12.)

Alvier divides this great genus into the following sub-genera:—

The Vultures properly so called, *Vultur*, Cuv.—These have a large and strong beak, with the nostrils placed diagonally at its base; the head and the neck without feathers and without caruncles; a collar of long feathers or of down at the bottom of the neck. The species are found on the ancient continent.

Sarcoramphus, Duméril.—America, Cuvier remarks, produces Vultures remarkable for the caruncles which surmount the membrane of the base of their beak, which is as large as that of the preceding genus, but the nostrils are oval and longitudinal. These are the *Sarcoramphi* of Duméril.

Cathartes, Cuv. (*Gallinazos*, or *Catharistes*, Vieill.).—These have the beak of the *Sarcoramphi*, that is to say, it is stout, and the nostrils are oval and longitudinal; but there is no fleshy crest, although their head and neck are plumbeous.

Percnopterus, Cuv. (*Gypætos*, Bechst.; *Neophron*, Sav.).—The bill in this group is slender, long, a little convex above its curvature; the nostrils oval and longitudinal; and the head, but not the neck, denuded of feathers. These are birds of moderate size, and which do not approach the Vultures properly so called in extent of power; they are therefore more ravenous after carrion and all kinds of impurities which attract them from afar; even excrements are palatable to this filthy race. Illiger comprises both this and the preceding sub-genera under his *Cathartes*.

Under this sub-genus Cuvier places the Urubu, *Vultur Iota*, C. Bonap., of America.

The Griffons (*Gypætos*, Storr; *Phene*, Sav.).—These, Cuvier observes, are arranged by Gmelin under the genus *Falco*, but approximate more closely to the Vultures in their habits and conformation. Their eyes are placed à fleur de tête, their claws are proportionally weak, their wings are half opened in their state of repose, their crop projects from the bottom of the neck when it is full, but the head is entirely covered with feathers. Their distinguishing characters consist of a very strong beak, which is straight, hooked at the point, and convex on the hooked part; of nostrils covered with stiff bristles directed forwards, and a pencil of similar bristles under the beak. Their tarsi are short and feathered down to the toes; their wings are long, and the third quill is the longest.

Prince Bonaparte makes the *Vulturidæ* the first family of his first order, *Accipitres*, and notices the following sub-families and genera:—

a. *Vulturinae*.

Genera:—*Neophron*, *Cathartes*, *Sarcoramphus*, *Vultur*, and *Gyps*.

b. *Gypætinæ*.

Genus:—*Gypætos*.

It must be remembered that none but European and American birds are admitted into this arrangement.

The *Vulturidæ* of Mr. G. R. Gray form the first family of his first sub-order (*Accipitres Diurni*) of his first order (*Accipitres*). The following sub-families and genera are placed by Mr. Gray under this family:—

Sub-Family 1. *Gypætinæ*.

Genus:—*Gypætos*.

Sub-Family 2. *Cathartinae*.

Genera:—*Neophron*, *Cathartes*, and *Sarcoramphus*.

Sub-Family 3. *Vulturinae*.

Genera:—*Gyps* (Sav.); *Vultur*; and *Otoggys* (G. R. Gray).

Sub-Family 4. *Racaminæ*.

Genus:—*Gyphoierax*, Rüpp.; *Racama*, J. E. Gray—*Vultur* (*Gyphoierax*) *angolensis*.

We now proceed to give a few illustrative species:—

Vultur fulvus, the Griffon Vulture, is Le Griffon of the French; Weissköpfiger Geier of the Germans; Avoltoio di Color Castagno of the Italians.

Head and neck covered with close-set, short, white, downy feathers; lower part of the neck surrounded with a ruff of long, slender, white feathers, sometimes with a slight tinge. On the middle of the breast a space furnished with white down. The whole of the body, the wings, and the origin of the tail yellow-brown or Isabella colour; quills and tail-feathers blackish-brown; beak livid-yellow, cere darker; iris hazel; feet gray or light-brown. Total length exceeding four feet.

The female is larger than the male.

The young have a whitish down varied with brown on the head and neck; the rest of the body very bright yellow, marked with great spots of gray or white.

It is a native of the mountainous parts of the north of Europe, Silesia, the Tyrol, Dalmatia (where it is very numerous), Spain (abundant near Gibraltar), the Alps, the Pyrenees, Turkey, the Grecian Archipelago, the north of Persia, and the north of Africa.

Head of Griffon Vulture.

Griffon Vulture (*Vultur fulvus*).

The nest of this Vulture is generally formed upon the most elevated and inaccessible rocks, but it often builds on the highest forest-trees, and in Sardinia on the loftiest oaks, where the nest of brushwood and roots is more than three feet in diameter. The eggs, which are generally two in number, though some state that it occasionally lays as many as four, are of a dull-greenish or grayish-white, slightly marked with pale reddish spots, and with a rough surface. Like all the other *Vulturidæ*, it feeds principally upon dead carcasses, to which it is frequently attracted in very considerable numbers. "When it has once made a lodgment upon its prey, it rarely quits the banquet while a morsel of flesh remains, so that it is not uncommon to see it perched upon a putrefying corpse for several successive days. It

* Temminck describes it as flesh-coloured.

never attempts to carry off a portion even to satisfy its young, but feeds them by disgorging the half-digested morsel from its maw. Sometimes, but very rarely, it makes its prey of living victims, and even then of such only as are incapable of offering the smallest resistance; for in a contest for superiority it has not that advantage which is possessed by the Falcon tribes, of lacerating its enemy with its talons, and must therefore rely upon its beak alone. It is only however when no other mode of satiating its appetite presents itself, that it has recourse to the destruction of other animals for its subsistence. After feeding, it is seen fixed for hours in one unvaried posture, patiently waiting until the work of digestion is completed, and the stimulus of hunger is renewed, to enable and to urge it to mount again into the upper regions of the air, and fly about in quest of its necessary food. If violently disturbed after a full meal, it is incapable of flight until it has disgorged the contents of its stomach; lightened of which, and freed from their debilitating effects, it is immediately in a condition to soar to such a pitch as, in spite of its magnitude, to become invisible to human sight. In captivity it seems to have no other desire than that of obtaining its regular supply of food. So long as that is afforded it, it manifests a perfect indifference to the circumstances in which it is placed." (Bennett.)

V. cinereus appears to be the Vautour Arrian and Vautour Noir of the French; Cinereous or Ash-Vulture and Beugal Vulture of Latham; and Grauer Geier of the Germans. It is a native of Europe. It is found in lofty mountains, and the vast forests of Hungary, the Tyrol, and the Pyrenees; the south of Spain and Italy; accidentally in Dalmatia; more frequently in Sardinia; in Sicily; rarely in Italy, and never in the forests; very accidentally in Germany.

Its food consists of dead animals and carrion, but never of living animals, of which it shows fear; the least animal, says Temminck, terrifies it.

This is the genus *Gyps* of Savigny. Mr. Gould, in his great work on the 'Birds of Europe,' notices a deviation in this species from the true or more typical vultures, manifested in the partially bare neck, open ears, curved claws, and powerful beak.

Bengal Vulture (*Vultur (Gyps) cinereus*).

V. Ponticerranus, the Pondicberry Vulture. The adult is about the size of a goose; a long loose naked membrane or wattle takes its origin about an inch below the meatus auditorius, and widens into a rounded form in the middle; the whole head and neck naked and flesh-coloured, but there are some short scattered hairs thereon; crop

covered with a small brown down, and round it is a longer white down.

The young with the head and neck more or less clothed with short down. (Temmin.)

It is a native of Bengal (probably spread over the continent of India), Java, and Sumatra.

Pondicherry Vulture (*Vultur Ponticrianius*).

V. Indicus, the Indian Vulture, has the head and neck denuded of feathers; all the upper plumage Isabella-ash colour varied with brown

Indian Vulture (*Vultur Indicus*).

and whitish; lower parts spotless very bright yellow; a slight short deep brown down, close-set and very smooth, covers the breast; bill black, but the point lighter; naked skin of the head rusty ash. It is about the size of a turkey. Total length 3 feet 3 inches.

It is found in India and Ceylon.

It is very voracious. It lingers all day near the sea-shore to prey on the dead fish thrown up by the waves. The species lives generally on carrion, and is said to disinter corpses. The flight of these vultures is heavy, and, like their congeners, they sometimes assemble in vast numbers on the battle-field.

V. Kolbei, Kolbe's Vulture. This is the Stront-Jager of Kolbe, and the Chasse-Fiente of Temminck. The head is covered with downy ferruginous feathers, which are whitish on the back of the neck; a ruff of loose ferruginous or dirty white feathers round the back of the neck; cere blackish; iris black; back and wings ferruginous or gray-brown; quills black; belly rather lighter ferruginous; feet brownish; claws black. Size less than that of the Griffon Vulture, but in general aspect and plumage very like that species. It is however easily distinguished. In Kolbe's Vulture the feathers of the wings and of the lower parts are all rounded at the end. In the Griffon Vulture they are long and acuminate. In Kolbe's Vulture the ruff is neither so long nor so abundant as in the Griffon, and the adult is nearly entirely of a whitish-Isabella colour. The adult Griffon is uniform bright brown throughout.

It is found in Barbary, and different parts of Africa, India, and Java.

Kolbe's Vulture (*Vultur Kolbei*).

V. auricularis, the Sociable Vulture. This is the Oricou of Le Vaillant and the French; and Ghaip, with the preceding clapping sound, of the Namaqua Hottentots. It has the head and greater portion of the neck red and naked, with the exception of a few hardly discernible hairs; beak horn-coloured, tinged with yellow at its base; iris chestnut. The folds of red naked skin originate behind the ears, surround the upper part of them, and then descend several inches, being irregular in their outline and nearly an inch broad at their widest part. Throat covered with hairs inclining to black.

This gigantic species, a fit machine for assisting in the clearance of the soil of Africa from the putrid bodies of elephants, hippopotami, rhinoceroses, and giraffes, haunts the caverns of rocks, and is altogether a mountain bird. There its night is passed, and there among the lofty crags it retires to repose when it has sated its appetite. Le Vaillant saw large flocks of them perched at sun-rise on the precipitous crag-trees to their abodes, and sometimes the extent of the rocky region was marked by a continued chain of these birds. Their tails are worn down by friction against their craggy haunts and by the soil

of the plains, in consequence of the laborious efforts which they make to raise themselves into the air; when once on the wing however their flight is grand and powerful. They rise higher and higher, till their enormous bulk is lost to human ken; but though beyond the sphere of man's vision the telescopic eye of the bird is at work. The moment any animal sinks to the earth in death, the imperceptible vulture detects it. Does the hunter bring down some large quadruped beyond his powers to remove, and leave it to obtain assistance—on his return, however speedy, he finds it surrounded by a band of vultures, where not one was to be seen a quarter of an hour before.

It is a native of South Africa. It has been taken in the neighbourhood of Athens, and must be therefore added to the catalogue of European birds; but it does not appear in Mr. Gould's grand work of the 'Birds of Europe.'

Sociable Vulture (*Gypaetus auricularis*).

Gypaetus barbatus.—This is the celebrated Lämmergeier. It is the Avoltoio Barbuto of the Italians; the Weissköpfige Geier Adler, and Bartadler of the Germans; and Bearded Vulture of the English.

Head and upper part of the neck dirty white; a black stripe extends from the base of the beak, and passes above the eyes; another, arising behind the eyes, passes over the ears; lower part of the neck, breast, and belly, orange-red; mantle, back, and wing-coverts, deep gray-brown, but on the centre of each feather is a white longitudinal stripe; wings and tail-feathers ashy-gray, the shafts white; tail long, very much graduated; beak and claws black; feet blue; iris orange; eye surrounded by a red lid. Length about four feet seven inches.

According to the age of the bird the plumage varies as follows:—there are brown feathers more or less on the top of the head; those of the lower part of the neck, breast, and belly often terminated with black; the white stripe on the middle of the feathers of the back and the coverts of the wings more or less developed; the belly often of a gray brown or variegated with white; iris of a more or less deep orange colour.

The young in the first two years have the head and neck of a brown-black; the lower part of the body gray-brown with spots of dirty white; on the upper part of the back are great white spots; the mantle and the wing-coverts are blackish with brighter spots; quills blackish-brown; iris brown; feet livid.

It inhabits the highest mountains of Europe, Asia, and Africa, the chain of the Pyrenees, and the Helvetic Alps, Sardinia, Greece, and the Tyrol. In Asia, the chain of the Caucasus, the Himalaya Mountains, the Siberian and Persian Mountains. It is also found in the lofty mountains of Central Africa and towards the borders of the Red Sea, principally in the most inaccessible parts of those mountains, and where there is plenty of the larger sort of game.

"Unlike the typical vultures," says Mr. Gould, "which are distinguished by their bare cheeks, indicative of their propensity for feeding on carrion, the Lämmergeyer has the neck thickly covered with feathers, resembling those of the true eagles, with which it also accords in its bold and predatory habits, pouncing with violent impetuosity on animals exceeding itself in size; hence the young Chamois, the Wild Goat, the Mountain Hare, and various species of birds find in it a formidable and ferocious enemy. Having seized its prey, the Lämmergeyer devours it upon the spot, the straight form of their talons disabling them from carrying it to a distance. It refuses flesh in a state of putrefaction, unless sharply pressed by hunger; hence nature has limited this species as to numbers: while, on the other hand, to the Vultures, who are destined to clear the earth from animal matter in a state of decomposition, and thus render the utmost service to man in the countries where they abound, she has given an almost illimitable increase."

Bearded Vulture (*Gypaetus barbatus*).

Neophron percnopterus. This is the Vautour Ourigourap of Le Vaillant, the Rhachamah or Pharaoh's Hen of Bruce and others, Avoltoio Aquilino and Caporaoccajo of the Italians, and Maltese Vulture of Latham. Head and only the front of the neck covered with a naked skin of a livid yellowish colour; the whole plumage pure white, except the great quill-feathers, which are black; feathers of the occiput long and loose; cere orange, iris yellow, mandibles blackish; feet livid yellow, claws black, tail very much graduated. Length two feet and a few inches.

According to age, the bird varies in its plumage, being either deep brown spotted with rusty, or bright gray-brown varied with white and yellow feathers. In this state the naked part of the head is livid, the cere white slightly tinged with orange, the iris brown, and the feet livid white.

The young in the first year have the naked part of the head livid, covered with a thin gray down; cere and feet gray ash; the whole plumage deep brown varied with yellowish-brown spots; greater quill-feathers black; iris brown.

It is found (very rarely) in the north of Europe, in Switzerland in the neighbourhood of Geneva. Very common in Spain on the Pyrenees, Portugal, Malta, Turkey, and in the Archipelago. Nowhere so abundant as in Africa. Russia as far north as Astracan, Arabia, Persia; the Deccan (Col. Sykes).

In October, 1825, one of these birds was killed near Kilve in Somersetshire. It was, when first seen, feeding upon a dead sheep, and had so gorged itself with flesh, that it was either incapable of flight or indisposed for exertion, and was easily shot. At the same time, another bird, apparently of the same species, was seen in the neighbourhood, but escaped.

This vulture does not congregate, except when an all-attractive carcass calls them together, but goes in pairs, the male and female seldom parting company. "In the districts which this species

inhabits," says Mr. Yarrell, "every group of the natives has a pair of these vultures attached to it. The birds roost on the trees in the vicinity, or on the fences which bound the inclosures formed for their cattle. They are to a certain degree domiciled and harmless. The people do them no injury: on the contrary, they are glad to see and encourage them, because they clean the premises of all the offal and filth they can find. In default of other food they eat frogs, lizards, and snakes."

Egyptian Vulture (*Neophron percnopterus*). (Gould.)

Sarcorampus papa, the King Vulture, or King of the Vultures. This is the Cozcaquauhtli (Queen of the Vultures) of the Mexicans (Hernandez). The naked skin of the head and neck brilliantly coloured. Beak reddish, with a shade of black; cere bright orange, prolonged between the nostrils into a comb about an inch and a half long, loose in texture, and falling on either side of the bill when the head is erect. Round the eye a scarlet circle; iris nearly colourless; side of the head purplish black. Back of the head covered with short down inclining to black. On each side behind the eye several broad and deep wrinkles of the skin, whence rises a thick and prominent fold extending obliquely downwards along the neck, reddish-brown mixed with blue, and marked with many lines of small black hairs. From the bright red upper part of the neck the colour gradually lessens in intensity, fading into orange and yellow towards the lower part. Round the bottom of the neck is a broad ruff of soft, downy, deep ashy-gray feathers.

Young of the Year, &c.—Deep bluish, with the exception of the abdomen and lateral tail-coverts, which are white. In the next year the young becomes dusky, marked with longitudinal white spots, and up to that time the greater portion of the head and neck is blackish-violet. The colouring which marks the adult is assumed in the third year, excepting a few black feathers among the upper coverts of the wing.

With a highly developed sense of smelling and a piercing sight, the expanse and strength of the wing of the King Vulture enables it to reach a lofty height, and there remain, bringing its powers of observation to bear over a wide tract of country. Patient under hunger, this vulture is said never to attack birds and quadrupeds, however small, while they are alive, though, when pressed with hunger from the want of its favourite carrion, it will feed upon snakes and lizards. This bird is found occasionally in Florida, in the United States, which is probably the northern limit. It is common in Paraguay, but, according to D'Azara, not going beyond 32° S. lat. Between the limits, especially towards the central parts of America, it appears to be abundant.

King Vulture (*Sarcorampus papa*).

Vultur leuconotus, the Chinese Vulture. This bird is brownish-black; lower part of the back white, as are the wings beneath and the inside of the thighs; when the wings are closed the white on the back is not seen; head brownish-black with short dark hairs; back of the neck covered with whitish down, the front of it livid flesh-colour and bare; at the bottom of the back of the neck is a dirty white ruff; on each side white feathers lap over the bottom of the neck and the crop; the cere is blackish; the bill horn-colour, black at the tip; iris dark; legs dirty brown-white with black scales; claws black. It is the size of a turkey.

Chinese Vulture (*Vultur leuconotus*).

W

WACHENDORFIA, a genus of Plants belonging to the natural order *Hamodraceae*, named after E. J. Wachendorf, professor of botany at Utrecht. It has an inferior flower, with 6 permanent withering irregular oblong parts; the 3 upper ones most erect, of which the two lateral ones have each a spur at the base; the 3 lower ones widely spreading. The stamens are 3, with thread-shaped, divaricated declining filaments, shorter than the corolla; the anthers oblong, incumbent. The ovary is superior, roundish, with 3 furrows; style thread-shaped, declining; the stigma simple, tubular. The fruit is a 3-lobed triangular-obtuse compressed capsule, with 3 valves, and 3 cells. The seeds are solitary, rough or hairy, and compressed.

W. thyrsifolia, Tall-Flowering Wachendorfia, has perennial smooth leaves, with a close oblong panicle. It is a native of the Cape of Good Hope, and thrives well in greenhouses in this country, and it will grow in the open air in fine seasons in May and June. The flowers are of a fine golden colour. The root is perennial, and of a saffron or red colour. Many of the plants belonging to *Hamodraceae* yield a matter used for dyeing, and De Candolle remarks that it is probable the species of *Wachendorfia* might be used for the same purpose.

WACKÉ, a barbarous name formerly much employed by German geologists, and thence introduced into English geology. It is regarded as a soft and earthy basalt, but has been used in other senses, and rather indefinitely. (Ansted, *Elementary Geology*.)

WAD. [MANGANESE.]

WADING-BIRDS. [GRALLÆ; GRALLATORES.]

WAGEL. [LARIDÆ.]

WAGNERITE, a Mineral, consisting of *Fluophosphate of Magnesia*. Its primary form is an oblique rhombic prism. Fracture uneven. Colour yellow, of different shades; often grayish. Streak white. Hardness 5.0 to 5.5. Lustre vitreous. Translucent. Specific gravity 3.11. It is found in the valley of Holgraben in Salzburg. It contains phosphoric acid, hydrofluoric acid, magnesia, oxide of iron, and oxide of manganese.

WAGTAILS. [MOTACILLINÆ.]

WAHLENBERGIA, a genus of Plants named after Wahlenberg, author of the 'Flora Japonica' and other works. It belongs to the natural order *Campanulaceae*, and many of the species embraced in it were formerly included under the genus *Campanula*. The species consists chiefly of herbs, which are for the most part annual. The leaves are mostly alternate, sometimes opposite, and are generally found in greatest abundance at the lower part of the plant. The flowers are seated on long peduncles, drooping at first, but erect in fruit. The calyx is 3-5 cleft; the corolla 3-5 lobed at the apex, rarely divided to the middle. The stamens 3-5 in number, free, the filaments broadest at the base. The style inclosed, pilose, especially at the upper part; stigmas 2-5. The ovary combined with the tube of the calyx. The capsule 2-5-celled, opening by as many valves as cells at the apex, each bearing a dissepiment in the middle. The seeds very numerous and minute. Above 50 species of plants belonging to this genus have been described. They are most abundant in the southern hemisphere, and are particularly numerous at the Cape of Good Hope. The following is one of the most remarkable forms presented by the genus:—

W. hederacea, Ivy-like Wahlenbergia, is a glabrous plant with slender ascending stems; the leaves are placed on long petioles, cordate, and bluntly 5-7 angled; the corolla 5-lobed at the apex, four times longer than the lobes of the calyx; the capsule hemispherical. This plant is a native of the west of Europe and of North America: it is abundant in Great Britain in Cornwall and Sussex, and is also found in Epping Forest. It is also a native of Scotland and Ireland. This plant was called *Aikinia hederacea* by Salisbury, in honour of John Aikin, a British botanist. It is the *Campanula hederacea* of Linnaeus, who was followed by Smith, Hooker, and others.

WALAN, the name of a tree in Amboyna, which was first described and figured by Rumphius, in his 'Herbarium Amboinense,' and called by him *Ichthyoclonos montana*. It is a large tree, and much valued by the natives of the island in which it grows. It is very rare, and the description of Rumphius is too imperfect to allow at present of its being assigned to any particular division of the vegetable kingdom.

The inhabitants of the isle of Amboyna use the bark of the roots for catching fish. Before it is used for this purpose it is powdered, and this process by the natives is always attended with a peculiar ceremony. The bark of the root is the part of the tree employed, and when it is collected for fishing, a large party attends. It is powdered by a single individual with a large stone, and whilst this process is going on, the rest lie round the stone in a circle; when all is over, a signal is given by one of them crowing like a cock; they then arise and collect the powder into little baskets which is reserved for use. In catching the fish other ceremonies are employed. The party goes in the morning early, and after throwing the powder upon the water and mixing it till it foams, they cast a net over the river, and then retire from the river, maintaining a death-like silence till the

poison has acted on the fish. In the course of an hour the net is generally found full of half-dead fish. The fish will recover from the effect of the poison if thrown into fresh-water, and are quite wholesome as food, although they will not keep so long as fish caught by other means. Rumphius procured some of the bark, and, omitting the ceremonies, found it a very successful mode of fishing.

WALCHIA, a genus of Fossil Plants. [COAL PLANTS.]

WALKE'RA, a genus of Plants named after Richard Walker, D.D., founder of the botanic garden at Cambridge. It belongs to the natural order *Ochnaceae*, and is known by possessing 5 petals, 5 stamens with ovate anthers; an obovately kidney-shaped fruit, which is a drupe; an inverted embryo with a hooked beak. There are two species of this genus known. *W. serrata* has serrate crenate leaves, racemes of flowers somewhat corymbose, and the lobes of the calyx lanceolate. It is a native of Malabar and Ceylon, and has yellowish flowers and reddish fruit. The roots and leaves are very bitter, and are used in decoction by the inhabitants of Malabar as a tonic and anthelmintic. *W. integrifolia* is a native of French Guyana, and has entire leaves.

WALL-CRESS, the common name of the Plants belonging to *Arabis*, an extensive genus in the natural order *Cruciferae*. Nearly 70 species of this genus have been described; they are most of them small plants, fond of growing in dry stony places and on walls, and hence their English name Wall-Cress. Their fruit is a linear siliqua, with flat 1-nerved valves. The seeds are oval or orbicular, compressed, in one row in each cell; the cotyledons are flat. The radical leaves are usually stalked, whilst those of the stem are sessile, or embrace the stem; they are entire or toothed, rarely lobed. The whole plant is frequently covered with hairs, of which those on the stem are simple, whilst those on the leaves are bifid or trifid. The flowers are white in most instances, rarely red. Several of the species are natives of Great Britain, and many of them are cultivated in gardens on rock-work and flower-borders, on account of their blooming early in spring.

A. turrata, Tower Wall-Cress, has leaves embracing the stem; the pods all on one side, recurved, flat, and linear; the bracts foliaceous. This plant is a native of Europe, in Spain, France, Switzerland, and Italy. In Great Britain it appears to be almost an entirely academical plant, as the only localities mentioned are the walls of colleges at Oxford and Cambridge.

A. hirsuta, Hairy Wall-Cress, has hairy toothed leaves, numerous straight pods, and the pedicels the length of the calyx. It is a native of middle and northern Europe, and also of North America, from Hudson's Bay to the Rocky Mountains. In Great Britain it is found in Sussex, Norfolk, and Suffolk, and also in Scotland.

A. rosea, Rose-Flowered Wall-Cress, has oblong subcordate half-stem-clasping leaves, covered with branched hairs; the pedicels longer than the calyx, and the stigma apiculate. It is a native of Calabria, and has rose-purple flowers.

A. albidia, White-Leaved Wall-Cress, has toothed leaves, hoary or downy, with branched hairs. It is a native of Taurida and the Caucasus. It has large white flowers, and is a tufted plant, often cultivated in English gardens.

WALL-FLOWER. [CHEIRANTHUS.]

WALL-PELLITORY. [PARIETARIA.]

WALL-RUE. [ASPLENIUM.]

WALL'CHIA, a genus of Plants belonging to the natural order *Byttneriaceae*, named in honour of the late Dr. Wallich, superintendent of the East India Company's Botanical Garden at Calcutta.

WALNUT-TREE. [JUGLANS.]

WALRUS. [PHOCIDÆ.]

WALTHERIA, a genus of Plants belonging to the natural order *Sterculiaceae*, named after three botanists of the name of Walther and Walter. The genus is known by possessing a 5-cleft calyx, furnished with a lateral 1-3-leaved deciduous involucre; 5 petals; a single style with tuberculated or pencilled stigma; a 1-celled, 2-valved, 1-seeded capsule. The species are small shrubs, with small usually yellow-coloured flowers, disposed in axillary or terminal stalked heads, rarely in panicles, rising in clusters from the branches.

W. Durandinha has a suffruticose ascending stem, with ovate or ovato-orbicular leaves, obtuse, and cordate at the base; the lower ones pilose, the upper ones tomentose and glaucous; the heads of the flowers terminal and axillary; the calyx pubescent; the petals bearded above the claw; the tube of the stamens entire. This plant is a native of Brazil, on the banks of the river Uruguay, where it is called *Durandinha*, or *Douradinha*. This plant, like the whole of the order to which it belongs, contains much mucilaginous matter, and is used in decoction in the Brazils, as a remedy in diseases of the chest, and also in some of the forms of venereal disease. It is also used as an external application to wounds.

WANDEROO. [MACAOUS.]

WAPITI. [CERVIDÆ.]

WARBLERS. [SYLVIADÆ.]

WARNERIA, a genus of Plants named after Mr. Warner. This genus, which is now called *Hydrastis*, has but a single species. It belongs to the natural order *Ranunculaceae*. The calyx is composed of three ovate sepals. The petals are wanting. The stamens and ovaries are numerous. The fruit is baccate, numerous, collected into a head; 1-celled, 2-seeded.

H. Canadensis is a small perennial herb, with tuberous roots. It is a native of North America, in watery places in tracts along the Alleghany Mountains, from Canada to Carolina. The head of its fruits very much resembles that of the raspberry. The root of this plant has been used both for dyeing and in medicine. It gives a beautiful yellow colour, and on that account has been called yellow-root. It is bitter, and acts on the system as a tonic, and for this purpose is recommended by Professor Barton.

WART-CRESS. [SENEBIERA.]

WART-HOG. [SUIDE.]

WARWICKITE, a Mineral, occurring in prismatic crystals of a brownish to an iron-gray colour, often tarnished, bluish, or copper-red. Lustre metallic, pearly to imperfectly vitreous or resinous. Hardness 5 to 6. Specific gravity 3 to 3.3. It is infusible before the blow-pipe. It is an American mineral, and is found in Magnesian Limestone. Professor Shepard says it is a fluo-titanate of iron, with some yttria. It has since been examined by Mr. Hunt, who says it contains no fluorine, and pronounces it to be a silicate and titanate of iron, magnesia, and alumina, with 7 per cent. of water. He calls it *Encladite*. (Dana, *Mineralogy*.)

WASHINGTONITE. [TITANIUM.]

WASPS. [VESPIDÆ.]

WATER, in its liquid, æiform, or solid state, is universally diffused through nature. It was once considered as one of the four elements, and is in common language still frequently so termed. Water however is now known to be a compound substance, consisting of hydrogen and oxygen, in the proportion of two volumes of the former gas and one volume of the latter; or by weight it is composed of 1 equivalent of hydrogen, 1, and 1 equivalent of oxygen, 8, = 9, its equivalent: it is in fact a protoxide of hydrogen.

Water is colourless, transparent, inodorous, and insipid; it is an imperfect conductor of heat and electricity; it is very slightly compressible, yielding only about 46.65 millionths of its bulk to the pressure of the atmosphere. Its specific gravity is 1, being the unit to which the density of all liquids and solids is referred, as a convenient standard, on account of the facility with which it is obtained in a pure state. A cubic inch of water at 62° Fahr., and 30 inches barometric pressure, weighs 252.458 grains, and as a cubic inch of atmospheric air weighs 0.31 grains, it is rather more than 815 times heavier than an equal volume of air.

Water, like all other fluids and substances, expands by exposure to an increase of temperature, and, with a curious exception, the dilatation within certain limits is proportionate to the degree of heat to which it is subjected. When water is cooled to 40° it is at the point of its greatest density, it then goes on expanding as it cools till reduced to 32°, when it solidifies, and this constitutes the exception to the law of contraction by reduction of temperature. If water at 40° be heated, it expands as the temperature rises, and this is conformable to the general law. This expansion of water by cold produces very important effects in the economy of nature; for if it increased in density, the frozen portions would sink down successively, and thus large bodies of water would become masses of solid ice.

The force with which water assumes the solid state is so great, that iron vessels of great thickness have been burst by it; and glass-vessels or lead-pipes are well known to be destroyed in winter time from the same cause. Ice is lighter than water, its density being 0.94, and hence it floats on water.

Water is commonly divided into certain heads, according to the source whence it is obtained, namely, into Atmospheric Water, including rain and dew; and into Terrestrial Water, comprising springs, river, well, lake, marsh, and sea-water; and, lastly, Mineral Waters. Water is seldom found in a state of perfect purity, but, from its great solvent and absorbent power, it is impregnated with a variety of saline substances, gases, and animal and vegetable substances, either living or undergoing a process of decomposition. The effect of these is to communicate different properties, and generally give it a peculiar taste, and not unfrequently an odour, which, if not cognisable by the blunted senses of man, is so by animals, especially the camel, which can secut water at a great distance in the desert. The specific gravity is often much increased, especially that of sea-water and of mineral-waters, from the saline ingredients, and of some of the great rivers, from the quantity of mud and other matters which they contain.

Rain-Water is commonly reckoned the purest; but it is by no means so free from accidental impregnations as is generally supposed. Whatever foreign ingredients exist in the atmosphere of any place are brought to the ground by the first rain that falls—thus it often contains nitric acid, carbonic acid, and chlorine; minute quantities of iron, nickel, and manganese; as well as of a peculiar organic substance, chemically different from the extractive matter and the gluten of plants and animals, called Pyrrhine. (Daubeny, 'Report,' p. 1.) Occasionally phosphoric acid is found in it, especially when the wind blows from the north-west. Much more important is the presence of

ammonia, first pointed out by Liebig ('Chemistry in its Application to Agriculture') as the chief source of the nitrogen found in plants. Rain-Water, from its great purity, has high solvent powers, which fit it well for the part it has to perform in the economy of nature, and also for many operations in the laboratory. In this respect it is nearly equal to distilled water. When collected in the neighbourhood of towns however, it requires to be boiled and strained; and is always contaminated with some soluble and generally dangerous salt of lead, when collected from leaden-roofs or transmitted through leaden pipes or cisterns.

Dew differs little from rain, save in containing more atmospheric air. Ice-Water differs, when first obtained, from rain, it being destitute of atmospheric air, and hence it cannot sustain respiration in fishes; it is for the same reason mawkish and insipid; but by exposure to the air it speedily absorbs a due proportion. Snow-Water is nearly similar.

Spring-Water is of various degrees of purity, according to its source and the strata through which it passes. Its most common source is rain, which percolates through some of the superficial strata, and, meeting with some obstacle, is forced up to the surface. Hence it contains most of the ingredients found in rain-water, and frequently also various saline principles, especially chloride of sodium and salts of lime; when these last are abundant, the water is what is termed 'hard,' though this quality is derived in some cases from other saline principles. "Large springs are in general purer than small ones, and those which occur in primitive countries, and in siliceous rocks or beds of gravel, necessarily contain the least impregnation." (Dr. Paris.) Such is the great purity of some springs, that their specific gravity is almost the same as distilled water. The specific gravity of the spring at Malvern is only 1.0002.

All spring-waters are more or less charged with carbonic acid gas. The sources of this are various, but the following may be mentioned:—

1. The atmosphere. Water has the power of absorbing carbonic acid gas, and that which is contained in the atmosphere, resulting from combustion, respiration, and other processes, is absorbed by water.

2. The decay of animal and vegetable matters and soils, through which waters percolate supply a certain quantity of carbonic acid. All the wells in London which receive water from the surface drainage contain so large quantities of carbonic acid as to render them sparkling and more pleasant to drink; although the source of the carbonic acid points out the dangerous nature of the waters.

3. Water passing through strata in volcanic districts is frequently charged to a great extent with carbonic acid, as the waters of Carlsbad, Spa, Pyrmont, Selters, and many other places on the continent of Europe. This would seem to arise from the carbonic acid, in combination with lime and other materials in the interior of the earth, being set free by the internal heat of the earth, finding its way to the strata, through which springs flow.

Spring waters contain saline constituents, according to the nature of the strata through which they flow. Waters percolated from the filth of a town, as in the well-waters of London, contain large quantities of chloride of sodium. Nitrates are found as the result of the decomposition of nitrogeneous matters, and also sulphates and phosphates from the same source. Water from the chalk contains carbonate of lime. The springs near the salt-mines of Cheshire contain chloride of sodium, also iodine and bromine. In the neighbourhood of deposits of oxide of iron or sulphure of iron, the springs become impregnated with this substance. When a water contains so large a quantity of any of these substances as to have its physical characters much altered, it is called a Mineral-Water, or Mineral-Spring. The study of the composition of mineral-waters throws much light on the composition of the rocks through which they have passed.

Dr. Gairdner, in his 'Natural History of Mineral and Thermal Springs,' has endeavoured to generalise the connection between the composition of mineral-waters and the rock formations from which they flow:—

"1. The salts held in solution in mineral-waters have often no connection with the acid, saline, or earthy matters which enter into the composition of the rocks which they traverse in their passage to the surface of the earth, which seems to be the first index that such waters cannot derive their origin from these formations.

"2. The mineral-waters of the primitive formations are almost all thermal, and generally possess a very high temperature. Their predominant impregnation is usually sulphuretted hydrogen gas, free carbonic acid gas, carbonate of soda, and in general salts with a base of soda, silica, few calcareous salts, except the carbonate of lime in some peculiar situations, and but a small quantity of iron.

"3. The waters of the transition and older secondary formations participate in those belonging to the primitive rocks. They are generally of a lower temperature, though some of them are still very hot; free carbonic acid is much less common, and sulphuretted hydrogen is almost entirely absent. Salts of soda still predominate, but the carbonate is not so common, and the sulphate of lime is found in the greater number of these waters. Silica exists in two or three examples.

"4. The waters of the newer secondary and tertiary formations are as distinctly characterised as those of the primitive rocks, placed at the other extremity of the series. They are all cold. Free carbonic

acid is almost entirely absent. Their predominating ingredients are the carbonate and sulphate of lime, sulphate of magnesia, and oxide of iron.

"5. The trachytic and basaltic formations, and modern volcanic rocks, present in their mineral waters many of the circumstances of temperature and composition which are found in the waters of the granite and other primitive rocks. Sulphuretted hydrogen, carbonic acid, carbonate of soda, carbonate of lime, and silica reappear, and many contain the free sulphuric and muriatic acids. The sulphate of lime, magnesian salts, and oxide of iron are again wanting. Thus, even in the present imperfect state of the science, the phenomena of mineral waters coincide with other geognostic observations, in placing below the granite the nigrin of the volcanic formations.

"6. It is often found that the mineral waters of a district have almost the same composition, in which case they generally issue from the crystalline and independent formations. In other cases they are subject to great varieties within a comparatively limited space, so that waters of a totally different composition rise close to each other, when they emerge from sedimentary rocks." (Gairdner, p. 242.) [SPRINGS, MINERAL, in ARTS AND SC. DIV.]

One of the next obvious practical distinctions between spring waters is that of thermal and cold. It is found that springs vary in temperature, according to the heat of the strata through which they pass. This is sometimes so great as to become very obvious to the senses. Though had recourse to for medicinal purposes, these springs naturally heated are not found to be more beneficial than those artificially heated. The medical use of the thermal springs has however served to mark their presence in many spots. Thus they are found in this country at Matlock and Buxton, and also at Bath and Bristol. On the continent at Aix-la-Chapelle, Baden Baden, in the Pyrenees, and many other places. Thermal springs are found in connection with volcanic action, and usually where this action is greatest the springs are warmest. This is seen in the Geysers of Iceland. [GEYSERS.] Heated waters dissolve up a larger quantity of saline constituents than cold waters, hence the amount of change produced by thermal waters is greater than that produced by cold.

Another class of substances which are found in all waters, and which give to many of them a special character, are organic matters. Living organisms, as the microscopic forms of *Algae* [DIATOMACEÆ; DESMIDIEÆ], are common in almost all kinds of water, and a large number of plants and animals belonging to higher classes live in water. These die and decompose, and before they are resolved into chemical compounds of the organic elements are found in the form of fermenting and putrefying matters, which when taken into the animal system appear capable of producing a tendency to disease. These substances however are not so common in spring-waters as in river-waters. Some of them have been supposed to have a definite chemical nature, and have been named Glacrine, Zoogene, Baregene, &c. (Lankester, 'Askern and its Mineral Springs'.)

River-Water mostly originates in springs, augmented by rain-water. If it flows over sand or granite, it is found very pure, depositing in its course many earthy salts, especially the calcareous ones, from the escape of carbonic acid. This circumstance renders the water rapid, and less pleasant to drink than spring-water. It possesses however the property of absorbing and retaining oxygen; hence the surface-water both of rivers and the ocean holds more oxygen than the atmospheric air, to the amount even of 29.1 per cent. (Daubeny, p. 6.) This contributes both to the maintenance of the respiration of fishes and growth of aquatic plants, which last are one source of the supply of the oxygen. The abundant supply of water furnished by large rivers offers a great temptation to procure thence the immense quantity required for the use of the inhabitants of towns on their banks. This may or may not be a wise proceeding, according to the nature of the water. If hard, it can only be rendered fit for domestic purposes, such as cooking and washing, by chemical processes, or by long boiling in appropriate boilers. When, in addition to its saline impregnations, numerous adventitious ones, many of a disgusting and most revolting nature, are found, it is clear that such water is very unfit for the use of man. This is unhappily the case with the Thames water furnished to the inhabitants of London; and although the plan of diverting the sewage will get rid of a very objectionable quality in the water, it will leave unaffected the causes of the hardness of the water, which has a less obvious but still very serious influence on the health and comfort of the inhabitants. This is clearly shown in the evidence before the Commission on the Health of Towns, particularly that of Professor Clark of Aberdeen, whose simple process, if adopted by the various water companies, would remove almost every one of the inconveniences; and while costing little, would be attended with a vast saving of soap, soda, and labour, along with a diminution in the tear and wear of linen and everything required to be washed in it.

Lake-Water varies much in its composition. The main difference depends on the lake possessing an outlet or being destitute of one. The water of the former generally corresponds with that of the rivers which flow into it; but the flow becoming slower, there is more scope for the development of animal and vegetable life, and for the decomposition of organic remains. Those destitute of an outlet are mostly

salt-water lakes, containing the same ingredients as the ocean, but in a more concentrated state. (Daubeny, p. 6.) Some lakes abound in tinal, such as the borax-lakes of Tibet.

Marsh-Water is stagnant, and abounds in animal and vegetable remains, either in a state of decomposition or passing into new combinations, generally of a low grade, as the lowest members of the vegetable kingdom and those of each section of the animal are mostly aquatic. These waters are for the most part unwholesome, as they emit nephritic gases, and produce disease if used for drink. The amount of unwholesome gases may be greatly diminished by substituting an active vegetation for an effete one. If these be of a bitter and astringent kind, such as bog-bean and tormentil, it greatly lessens the tendency to disease in the cattle which drink them. Previous to employing them as drinks for human beings, steeping different plants, or rubbing the sides of the vessels with bitter seeds, render them, if not quite pure, at least less noxious. Thus the tea-plant is used by the natives of China and Japan, the *Strychnos potatorum* by those of India, and the bitter almond by those on the banks of the Nile. [STRYCHNOS.]

Impure or putrid water may be rendered pure by filtering through sand or charcoal, or by simply pouring it from one vessel to another in the sun.

The water of the ocean abounds in saline matters so much that it is unfit for dietetical purposes. The quantity of salt is not uniform, since the water of the Southern Ocean contains more salt than the Northern, while the proportion present in the water at the equator holds the middle place between the two. (Daubeny, p. 4.) Sea-water may be rendered fit for drinking by pressure, filtration, and freezing, or simply by boiling it, and condensing the steam as it arises. For an account of the composition of sea-water see SONIUM, and of the uses of water for alimentary purposes see FOOD.

WATER-FLY. [GYRINIDÆ.]

WATER-GUT. [ULVACEÆ.]

WATER-HEMLOCK. [CICUTA.]

WATER-HEN. [RALLIDÆ.]

WATER-LILY, the common name for the species of the family *Nymphæaceæ*. [NYMPHÆACEÆ.] One of the most beautiful and the largest of the tribe is the *Victoria Regia*. This splendid plant, in the dimensions of its leaves, their varied tints, the colour, size, and fragrance of its flowers, may deservedly be called the queen of flowers. The following is the account of its discovery by Sir Robert Schomburgk:—"It was on the 1st of January, while contending with the difficulties nature opposed in different forms to our progress up the river Berhice, that we arrived at a point where the river expanded and formed a currentless basin. Some object on the southern extremity of this basin attracted my attention; it was impossible to form any idea what it could be, and, animating the crew to increase the rate of their paddling, we were shortly afterwards opposite the object that had raised my curiosity—a vegetable wonder. All calamities were forgotten; I felt as a botanist, and felt myself rewarded;—a gigantic leaf, from five to six feet in diameter, salver-shaped, with a broad rim, of a light green above and a vivid crimson below, resting on the water. Quite in character with the wonderful leaf was the luxuriant flower, consisting of many hundred petals, passing in alternate tints from pure white to rose and pink. The smooth water was covered with the blossoms, and as I rowed from one to the other I always observed something new to admire." The leaves are very large, measuring five or six feet in diameter. They have an orbicular form, the upper surface is bright green, and they are furnished with a rim round the margin from 3 to 5 inches in height; on the inside the rim has a green colour, and on the outside, like the under surface of the leaf, it is of a bright crimson; they have prominent ribs, which project an inch high, radiating from a common centre; these are crossed by a membrane, giving the whole the appearance of a spider's web; the whole leaf is beset with prickles, and when young is convolute. The stock of the flower is an inch thick, and studded with prickles. The calyx is 4-leaved, each sepal is 7 inches in length and 4 inches broad; the corolla covers the calyx with hundreds of petals; when first opened it is of a white colour, but subsequently changes to pink; it is very fragrant. Like all other water-lilies, its petals and stamens pass into each other, a petal often being found surmounted with half an anther. The seeds are numerous, and imbedded in a spongy substance. This plant has by some botanists been placed in the genus *Euryale*, whilst Lindley thinks it is nearer *Nymphaea*, from which it differs in the sepals and petals being distinct, the papilla of the stigma being prolonged into a horn, and the changing colour of its petals.

This splendid plant has now been successfully cultivated in many of the hot-houses of this country. Beautiful specimens are to be seen in the Royal Gardens at Kew, and at the Crystal Palace, Sydenham.

WAVELLITE. *Hydrargillite*, *Devonite*, or *Lasionite*. This Mineral, which is a phosphate of alumina, was discovered by Dr. Wavel, hence its name. It occurs in globular concretions from a very small size to that of an inch in diameter; these consist of small slender crystals radiating from a centre, with imperfect terminations. Primary form of the crystal a right rhombic prism. Cleavage parallel to the lateral planes, and the greater diagonal of the prism. Hardness 3·5 to 4. It scratches carbonate of lime. Colour nearly white; gray, brown, yellow, and green of various shades. Lustre vitreous, somewhat pearly on the cleavage planes. Transparent, translucent. Specific gravity, 2·337. Before the blow-pipe it swells and becomes snow-white; when powdered, it dissolves without effervescence in nitric and sulphuric acids when heated, and gives out an acid which slightly corrodes glass.

This mineral is found at Barnstaple in Devonshire; near Cork, Ireland; in Cornwall, Germany, Brazil, &c.

Analysis of the mineral from Barnstaple, by (1) Fuchs, (2) Berzelius:

 WAYFARING TREE. [VIBURNUM.]

WEALDEN FORMATION, the uppermost series of the strata usually included by English geologists in the Oolitic System. [GEOLOGY.] This arrangement is justified by the plants, fishes, and reptiles which occur in the formation, for they are generically, and even specifically, more allied to Oolitic than to Cretaceous types of structure. But as the Wealden deposits are of fluvial origin principally, we do not find in them the usual shells or *Crustacea* of the Oolite, but a peculiar series, of which a few species are also discovered in other districts.

The Wealden beds comprise a series of layers of clay, sand, and shale, with subordinate beds of limestone, grit, and sandstone, which are more or less regularly distributed, and contain remains of fresh-

water *Mollusca*, as species of *Cyrena*, *Unio*, *Paludina*, &c. Fishes, *Sauria*, and Plants are also found in these deposits, with a few marine *Mollusca*. The following are the characters of the subordinate groups of the formation:—

1. WEALD CLAY.—Average thickness 140 to 200 feet.

Stiff clay of various shades of blue and brown; with subordinate beds of limestone and sand: <i>Sep-toria</i> .	<i>Paludina</i> , <i>Cypris Val-densis</i> , <i>Cyrena</i> , &c., the bones of reptiles rarely; scales and bones of fishes.	The Wealds of Sussex, Surrey, and Kent; forming the vale between the Downs and Forest Ridge.
---	---	--

2. HASTINGS SANDS.—Average thickness 400 to 500 feet.

Gray, white, ferruginous, and fawn-coloured sand, and friable sandstone, with abundance of small portions of lignite.	a. Horsted Sand. Traces of carbonised plants.	Little Horsted, Uckfield, Framfield, Bexhill, Chailley, Fletchling, Erldridge Park, Tunbridge Wells, &c.
---	--	--

b. Strata of Tilgate Forest.

Sand and friable sandstone, of various shades of green, yellow, and ferruginous, surface oftentimes deeply furrowed.	Ferns, and stems of vegetables, bones of Saurian animals, birds, turtles, fishes, &c.; shells of the genera <i>Unio</i> , <i>Cy-clas</i> , <i>Cyrena</i> , <i>Paludina</i> , &c.	Loxwood, Horsham, Tilgate, and St. Leonard's Forests; Chailley, Ore near Battle, Hastings, &c., Rye, Winchelsea.
Tilgate stone, very fine, compact bluish or greenish gray grit, in lenticular masses, surface oftentimes covered with mammillary concretions; the lower beds frequently conglomeritic, and containing large quartz pebbles.	Lignite wood.	

Clay or marl; of a bluish gray colour; alternating with sand, sandstone, and shale.	Bones, and shells but rarely. Ferns; and stems of vegetables.	Tunbridge Wells.
---	--	------------------

White and yellow friable sandstone and sand.	c. Worth Sandstone. Ferns and Arundina-ccous plants. Lignite, &c.	Worth near Crawley, St. Clement's Caves, Hastings, &c.
--	--	--

3. ASHBURNHAM BEDS.

A series of highly ferruginous sands, alternating with clay and shale, containing ironstone and lignite.	Ferns, Lignite, &c.	Lower part of Hastings Cliffs; near Buxted; West Hothly; Crawley, &c.
Shelly limestone, alternating with sandstone, shale, and marl; and concretionary masses of grit.	<i>Cypris</i> . Shells of the genera <i>Cyclas</i> and <i>Cyrena</i> ; lignite carbonised vegetables.	Archer's Wood, near Battle; Brightling, Pounceford, Burwash, Hurst Green, Eason's Green.

The Dover Railway traverses the beds of the Wealden between Red Hill and the branch-line to Tunbridge Wells, exposing the Weald Clay and Upper Hastings Sands.

The fossils of this group are as follows:—

<i>Carpolithes Mantelli</i> . <i>Clathraria Lyellii</i> , Mant. <i>Endogenites erosa</i> , Mant. <i>Equisetites Lyellii</i> , Mant. <i>Lonchopteris Huttoni</i> , Presl.	<i>Lonchopteris Mantelli</i> , Brong. <i>Pterophyllum Brongniarti</i> , Mant. <i>Sphenopteris Mantelli</i> , Brong. <i>S. Phillipsii</i> , Mant. <i>S. Sillimani</i> , Mant.

WEASELS. [MUSTELIDÆ.]

WEAVER-BIRDS. [PLOCEINÆ.]

WEBSTERITE. [ALUMINITE.]

WEEVIL. [CALANDRA; CURCULIO.]

WEINMANNIA, a genus of Plants belonging to the natural order *Cunoniaceæ*, named after John William Weinmann, a botanist. The species are trees, and natives of South America and the Mauritius. The leaves are compound or simple, with reticulated petioles; the calyx is permanent and 4-parted; the petals 4; stamens 8; an hypogynous, unceolated disc; the fruit a many-seeded capsule, opening at the dissepiments from the apex; the seeds are roundish and reniform. There are about 40 species of this genus described.

W. tinctoria is a native of the Isle of Bourbon; it has leaves with many pairs of leaflets, which are oblong, serrated, and smoothish; the joints of the rachis spatulate, and the fascicles of racemes many-flowered. This tree is called by the natives of Bourbon Tan Rouge, and is used for dyeing a red colour.

Most of the species of *Weinmannia* possess astringent properties, and may be used for dyeing. On this account they are also often employed in Peru to adulterate the various species of *Cinchona* barks which are collected for medicinal purposes.

WEISSITE, a Mineral, occurring in oblique rhombic prisms. Colour ash-gray or brownish. Presents only feeble traces of cleavage. Fracture even or coarse granular. Hardness, scratches glass, but is scratched by steel. Lustre pearly or hazy. Scarcely translucent. Specific gravity 2.30. Found at Fahlun, Sweden.

WELD. [RESEDA.]

WELLS. [SPRINGS; WATER.]

WELLS, MINERAL. [WATER.]

WENLOCK ROCKS. [SILURIAN SYSTEM.]

WENTLETRAP. [SCALARIA.]

WERNERITE. [SCAPOLITE.]

WESTRINGIA, a genus of Plants belonging to the natural order *Lamiaceæ*, named after Dr. Westring. The species are natives of Australia.

WETHERELLIA, a genus of Fossil Fruits.

WHALEBONE. [CETACEA.]

WHALES. [CETACEA.]

WHEAT. [TRITICUM.]

WHEATEAR. [SAXICOLA.]

WHEAT-FLY. [CECIDOMYIA.]

WHEEL-ANIMALCULES. [ROTIFERA.]

WHEELERA, a genus of Plants belonging to the natural order *Leguminosæ*, named after Mr. Thomas Wheeler. There is only one

species of this genus well made out, and this is a native of America. It is a tree furnished with stipular spines, simple crowded leaves, or trifoliate leaves, with the leaflets sessile. It is called American Ebony, and has the name *W. Ebenus*. It is chiefly a native of the West Indies, and is cut and sent to this country under the name of ebony, though it is a very different plant from the true ebony. The wood is very hard, of a brownish-green colour, and bears a fine polish, and is much employed by cabinet and musical instrument makers.

WHELK. [BUCCINUM.]

WHETSTONE. [SLATE.]

WHIDAH. [PLOCEINÆ.]

WHIMBREL. [SCOLOPACIDÆ.]

WHIN. [GENISTA.]

WHINCHAT. [SAXICOLA.]

WHIP-POOR-WILL, the common name of the *Caprimulgus vociferus*.

This bird is the *Wecollis* of the Delaware Indians; and Whippoorwill of Lawson, "so named," says the latter, "because it makes those words exactly. They are the bigness of a thrush, and call their note under a bush, on the ground, hard to be seen, though you hear them never so plain."

Mr. Nuttall remarks, that in the lower part of the state of Delaware, he found these birds troublesomely abundant in the breeding season, so that the reiterated echoes of 'whip-whip-poor-will,' 'whip-peri-will,' issuing from several birds at the same time, occasioned such a confused vociferation as, at first, to banish sleep. This call, he adds, is continued, except in moonlight nights, usually till midnight, when they cease until again aroused, for a while, at the commencement of twilight. They pass the day in repose, retiring to the deepest and darkest woods, usually those in elevated situations.

Whip-Poor-Will (*Antrostomus (Caprimulgus) vociferus*).

Caprimulgus Carolinensis, Chuck-Will's-Widow, or Carolina Goat-Sucker, is another species, remarkable for the articular nature of the sounds of its voice. It is also found in the United States.

Flying low, and skimming a few feet above the surface of the ground, it settles on logs and fences, from which it pursues the flying moths and insects on which it feeds; sometimes sailing nearer the earth, it alights to pick up a beetle, or flutters round the trunk of a tree in search of any insect that may be crawling on the bark. Mr. Nuttall, who thus describes its mode of taking its prey, adds, that, like the species above described, it commences its singular serenade of 'chuck-will's-widow' in the evening soon after sunset, continuing the cry with short interruptions for several hours, and renewing it towards morning till the opening dawn. The tones are slower, louder, and more full than those of the Whip-Poor-Will, and may be heard on a still evening for half a mile. "The species," says Mr. Nuttall in continuation, "is particularly numerous in the vast forests of the Mississippi, where, throughout the evening, its echoing notes are heard in the solitary glens and from the surrounding and silent hills, becoming almost incessant during the shining of the moon; and at the boding sound of its fine voice, when familiar and strongly reiterated, the thoughtful superstitious savage becomes sad and pensive."

The same author states that in rainy and gloomy weather these birds remain silent in the hollow log which affords them and the bats a common roost and refuge by day. When discovered in this situation they ruffle their feathers, open their enormous mouths, and utter a murmur, almost like the hissing of a snake, to intimidate the intruder.

"If," says Mr. Nuttall, "superstition takes alarm at our familiar and simple species, what would be thought by the ignorant of a South American kind, large as the Wood-Owl, which, in the lonely forests of Demerara, about midnight breaks out, lamenting like one in deep distress, and in a tone more dismal even than the painful hexachord of the slothful Aï. The sounds, like the expiring sighs of some agonising victim, begin with a high loud note, 'ha, ha, ha ha ha! ha! ha!' each tone falling lower and lower, till the last syllable is scarcely heard, pausing a moment or two between this reiterated tale of seeming sadness. Four other species of the Goatsucker, according to Waterton, also inhabit this tropical wilderness, among which also is included the Whip-Poor-Will. Figure to yourself the surprise and wonder of the stranger who takes up his solitary abode for the first night amid those awful and interminable forests, when at twilight he begins to be assailed familiarly with a spectral equivocal bird, approaching within a few yards, and then accosting him with 'who-are-you? who-who-are-you?' Another approaches and bids him, as if a slave under the lash, 'work-away, work-work-work-away;' a third mournfully cries 'willy-come-go! willy-willy-willy-come-go!' and, as you get among the highlands, our old acquaintance vociferates 'whip-poor-will, whip-whip-whip-poor-will!' It is therefore not surprising that such unearthly sounds should be considered in the light of supernatural forebodings issuing from spectres in the guise of birds." ('Manual of the Ornithology of the United States and of Canada.')

Chuck-Will's-Widow (*Caprimulgus (Antrostomus) Carolinensis*).

WICHTINE, a Mineral, with its cleavage parallel to the sides of a rectangular prism. Scratches glass. Colour black. Fracture flat, conchoidal. Found at Wichty in Finland. The analysis by Laurent gives—

Silica	56.3
Alumina	13.3
Protoxide of Iron	13.0
Peroxide of Iron	4.0
Soda	3.5
Lime	6.0
Magnesia	3.0

—99.1

WIDGEON, or WIGEON, the common name of the *Marca Penelope*, *Anas Penelope*, Linn.

This bird is the Canard Siffleur of the French; Anitra Fischiarola, Anatra Marigiana, and Fischione, of the Italians; Pfeifente of the Germans; Smient, Fluit-eend, and Halve-eend-Vogel, of the Netherlands; Wriand of the Swedes; Bles-and of the Danes; Whewer, Whim, Pundle, Pundle-Whim, Whew, Puddled Whew, Easterling, and Yellowhall, of the English; and Chwiw of the Welsh.

In the article DUCKS an illustration of the American Widgeon is given. We here give one of the Common Widgeon.

Widgeon (*Marca Penelope*), male and female.

WILLOW-WARBLED. [SYLVIADÆ.]
WILLOWS. [SALIX.]

WILLUGIIBEIA, a small East Indian genus of Plants belonging to the natural order Apocynaceæ, named after Francis Willughby, F.R.S.

W. Edulis, a native of Silhet and Chittagong, yields a milky juice, which concretes into an indifferent kind of elastic rubber or caoutchouc. The natives of the above districts eat the fruit, and esteem it good. The fruit of another species, *W. Martabana*, so called from the province of which it is a native, is yellow, and about the size of an orange.

WILSONIA, a genus of Plants belonging to the natural order Convolvulaceæ, named after Mr. John Wilson, of Kendal. Wilson was in an humble condition of life, and made great sacrifices for the purpose of enabling him to pursue his favourite study of botany. He is said to have been so anxious to possess Morison's work on plants, that he was about to sell his only cow to purchase it, when a benevolent lady in his neighbourhood presented him with a copy.

WINE. [FOOD; VITIS.]
WINE-TRAP. [CENOTHERA.]
WINGS. [BIRDS.]
WINTER ACONITE. [ERANTHIS.]
WINTER BERRY. [AQUIFOLIACEÆ.]
WINTER CHERRY. [PHYSALIS.]
WINTER GREEN. [PYROLA; TRIENTALIS.]
WINTERA. [WINTERACEÆ.]

WINTERACEÆ, a natural order of Exogenous Plants. This order is characterised by possessing hermaphrodite or unisexual flowers; from 2 to 6 sepals, which are sometimes not to be distinguished from the petals; the petals are from 2 to 30 in number, and, when more than 5, in several rows; the stamens are hypogynous, short, indefinite, and distinct, arranged in a single whorl, 1-celled; the embryo is very small and straight, and situated at the base of a fleshy albumen. The order consists of small trees or shrubs, with alternate, dotted, coriaceous, persistent leaves; convolute deciduous stipules; and solitary, sweet-scented, brown or chocolate-coloured flowers.

This order has obtained its name, given it by Brown, from *Wintera*, the old name of the *Drimys Winteri*. This name was given in honour of William Winter, a captain in the royal navy, who sailed round the world with Sir Francis Drake. It contains four genera—*Illicium*, *Tamus*, *Drimys*, and *Tasmannia*. [ILICIIDÆ.]

These genera constitute the section *Illicieæ* of the order Magnoliaceæ of De Condolle, and the section *Winteraceæ* of Lindley in the same order. They differ from *Magnoliaceæ* in their dotted leaves, and also in their aromatic qualities. There are about ten species, of which two are found in Australia, two in the hotter parts of America, two in South

and two in North America, one in China and Japan, and one in New Zealand.

Drimys Chilensis.

a, cutting, with flowers and leaves; b, flower separated; c, carpel.

Temus moschata is a shrub found in Chili. The berries resemble those of the coffee-plant, and are exceedingly bitter to the taste.

Drimys Winteri, the true Winter's Bark, is a tree from 6 to 40 feet in height, and is a native of the Straits of Magalhães and of Statenland. This tree was brought back from the Straits of Magalhães by Captain W. Winter. He had found it useful against scurvy in his ship's crew, and employed it both as a medicine and a condiment for food. [WINTER'S BARK, in ARTS AND SC. DIV.]

D. Granatensis, New Granada Winter's Bark, is a tree about 20 feet high, and grows in the mountains of New Granada and Brazil. In New Granada this tree is called Agi, and in the provinces of Quito and Popaya, Canela de Parama. Several varieties have been described. The bark of all of them is aromatic and stimulating, and is much used by the natives where they grow, both as a medicine and for seasoning their food.

Tasmannia aromatica is a native of Australia, especially in Van Diemen's Land. It possesses the same aromatic qualities as the species of the other genera of the family.

WIRE-WORM. This name is applied indiscriminately to the larvæ of several species of Beetle, which are injurious to the roots of corn and other plants. They mostly belong to the family of *Elateridae*, and the perfect insects, on account of their leaping movements, are called Skipjacks. The most common form of Wire-Worm in England is the larva of *Elater (Cutaphagus) sputator*. The last segment of the body of this larva is entire and long, resembling a bit of wire—hence the name given to these insects. [ELATERIDÆ.]

WISTARIA, a genus of Plants belonging to the natural order *Leguminosæ*, named after Caspar Wistar, professor of anatomy in the University of Pennsylvania. It has the following characters:—The leaves are unequally pinnate, and without stipules. The flowers are arranged in terminal racemes, and are of a blue lilac colour; when young they are accompanied by bracts which fall off as the flowers expand. The calyx is campanulate, somewhat bilabiate, the upper lip has two short teeth, the lower lip three teeth, which are subulate; the corolla is papilionaceous; the stamens diadelphous; a nectariferous tube guards the stipe of the ovary; the legume is coriaceous, 2-valved, 1-celled, and rather torulose. The species are deciduous twining shrubs, natives of North America and China. They grow vigorously in Great Britain, and form when in flower the handsomest ornaments of our gardens. The following are the species:—

W. frutescens, Shrubby Wistaria, has the wings of the corolla each furnished with two auricles; the ovary glabrous; the flowers odorous. This is an elegant climbing plant, and is a native of Virginia,

the Carolinas, and Illinois, in boggy places. The flowers open from July to September. They are of a bluish-purple colour, the standard having a greenish-yellow spot at the base. They give out a sweet scent.

W. Chinensis, Chinese Wistaria, has the wings of the corolla each furnished with one auricle; the ovary villose; the flowers large. This plant is a deciduous twiner, and is a native of China, and was introduced into this country in 1816. It flowers in Great Britain in May and June, and sometimes produces a second crop of flowers in August. This species was originally called *Glycine Chinensis*, a name which in some places it still retains.

WISTONWISH, a common name given to the *Arctomys (Spermophilus?) Ludovicianus*. It is a native of the banks of the Missouri and its tributaries.

According to Sir John Richardson it is the Prairie Dog of Gass; Prairie Dog, or Wistonwish, of Pike; Petit Chien, Prairie Dog, Barking Squirrel, and Burrowing Squirrel, of Lewis and Clark, but not the Burrowing-Squirrel of their third volume; *Arctomys Ludovicianus* of Ord and Say; *Cynomys Socialis et Cinerens* of Rafinesque-Smaltz; *Monax Missouriensis* of Warden; *Arctomys latrans* of Harlan; and Prairie Marmot of Godman.

Mr. Say states that this interesting and sprightly animal has received the name of Prairie Dog from a fancied resemblance of its warning cry to the hurried barking of a small dog. The sound, according to him, may be imitated by the pronunciation of the syllable 'chek, chek, chek!' in a sibillated manner and in rapid succession by propelling the breath between the tip of the tongue and the roof of the mouth. The assemblages of their burrows are denominated Prairie-Dog Villages by the hunters. They vary widely in extent: some are confined to an area of a few miles; others extend to a circumference of many miles. Mr. Say further observes that only one of these villages occurred between the Missouri and the Prairie towns; thence to the Platte they are much more numerous. He describes the entrance to the burrow as being at the summit of the little mound of earth brought up by the animal during the progress of the excavation below. These mounds are sometimes inconspicuous, but generally somewhat elevated above the common surface, though rarely to the height of 18 inches. Their form is that of a truncated cone, on a base of 2 or 3 feet, perforated by a comparatively large hole or entrance at the summit or in the side. "The whole surface," continues Mr. Say, "but more particularly the summit, is trodden down and compacted, like a well-worn pathway. The hole descends vertically to the depth of one or two feet, whence it continues in an oblique direction downward. A single burrow may have many occupants. We have seen seven or eight individuals sitting upon one mound. The burrows occur usually at intervals of about twenty feet. They delight to sport about the entrance of their burrows in pleasant weather. At the approach of danger they retreat to their dens, or when its proximity is not too immediate, they remain barking and flourishing their tails on the edge of their holes, or sitting erect to reconnoitre. When fired upon in this situation, they never fail to escape; or if killed, instantly to fall into their burrows, where they are beyond the reach of the hunter. As they pass the winter in a lethargic sleep, they lay up no provision of food for that season, but defend themselves from its rigours by accurately closing up the entrance to the burrow. The further arrangements which the Prairie Dog makes for its comfort and security are well worthy of attention. He constructs for himself a very neat globular cell with fine dry grass, having an aperture at top large enough to admit the finger, and so compactly formed that it might almost be rolled over the floor without injury."

Sir John Richardson observes that the Prairie Dog seems to differ from other American Marmots in the length of its thumb-nail, and to approach in that respect *A. fulvus* of Lichtenstein.

WITCH-ELM, or **WYCH-ELM**. [ULMUS.]

WITCH-HAZEL. [HAMAMELIDACEÆ.]

WITCHES'-BUTTER. [TREMELLINI.]

WITHAMITE, a Mineral occurring crystallised. Primary form an oblique rhombic prism; it is found also in small imbedded globular masses composed of radiating crystals. Fracture uneven. Hardness, scratches glass readily. Colour, red and reddish-white. Streak white. Translucent; opaque. Specific gravity 3.137. It is not acted on by acids. Before the blow-pipe intumesces and fuses with difficulty into a dark-gray scoria. With salt of phosphorus it dissolves with effervescence into a globule which contains a little silica, and becomes opaque on cooling. It is found at Glencoe in Scotland, and is regarded as a variety of *Epidote*. [EPIDOTE.]

WITHERINGIA a genus of Plants belonging to the natural order *Solanaceæ*, named after Dr. William Withering. The species are neither handsome nor useful.

WITHERITE. [BARTES.]

WITTELSBA'CHIA, the name of a genus of Plants belonging to the natural order *Ternströmiaceæ*. The species are now referred to *Cochlospermum*. [COCHLOSPERMUM.]

WOAD. [GENISTA; ISATIS.]

WÖHLERITE, a Mineral occurring in angular grains, and in tabular crystals. Form undetermined. Cleavage distinct in one direction. Colour light-yellow, wine-yellow, honey-yellow, brownish-yellow. Streak yellowish-white. Fracture more or less conchoidal, splintery. Hardness 5.5. Lustre vitreous. Subtranslucent. Transparent. Specific

gravity 3.41. Found in an island near Brevig in Norway. The analysis by Scheerer gives—

Silica	30.62
Columbic Acid	14.47
Zirconia	15.17
Lime	26.19
Soda	7.78
Oxide of Iron	2.12
Protoxide of Manganese	1.55
Magnesia	0.40
Water	0.24

—98.54

WOLF. [CANIS.]

WOLF-BERRY. [SYMPHORICARPUS.]

WOLF-DOG. More than one variety of the dog is known by this name.

The Wolf-Dog of Spain is nearly as large as a mastiff. The nose is pointed, the ears are erect, the coat long and fine, the tail bushy or feathered, and curling over the back. The colour is generally white with large fulvous or brown patches. Sometimes the coat is closer.

The Black Wolf-Dog of the Indians of Florida is described by Bartram as not differing from the wolves of the country excepting in its bark. That this animal is sagacious and trustworthy, appears from the fact that one was trained to watch and keep together horses without any human help.

The Irish Wolf-Dog is now very rare; and, indeed, the breed had been so crossed, that latterly two were seldom seen alike.

WOLF-FISH. [ANARRHICUS.]

WOLFRAM. [TUNGSTEN.]

WOLF'S-BANE. [ACONITUM.]

WOLKONSKOIT, a Mineral occurring amorphous. Structure compact. Fracture imperfect, conchoidal. Hardness 2.5. Colour light emerald-green. Streak bluish-green and shining. Opaque. Nearly dull. Specific gravity 2.2. It is so extremely fragile that it readily falls to pieces on a slight blow. It is found at Perm in Russia. It contains oxide of chromium, oxide of iron, silica, magnesia, and water.

WOLLASTONITE (*Tubular Spar*), a Mineral, consisting of Silicate of Lime. It occurs crystallised and massive. Primary form an oblique rhombic prism. Cleavage parallel to the terminal plane and horizontal diagonal. Fracture uneven. Hardness, scratched by phosphate of lime. Colour white, gray, yellow, red, and brown. Streak white. Lustre vitreous. Translucent, transparent. Specific gravity 2.805. The amorphous varieties are composed of columnar crystals lying in all directions, or fibrous, the fibres being either parallel or divergent. Before the blow-pipe on charcoal the edges are melted into a semitransparent colourless glass; but it requires a very great heat to fuse it perfectly; with borax it readily melts in large quantity into a transparent glass.

It is found in very perfect crystals at Vesuvius, at Capo di Bove near Rome, in the Bannat, Ceylon, North America, Sweden, &c.

WOLVERINE. [GULO.]

WOMBAT. [MARSUPIATA.]

WOOD. [EXOGENS; TISSUES, VEGETABLE.]

WOOD-APPLE. [FERONIA.]

WOOD-AVENS. [GEUM.]

WOOD-CHAT. [LANIADÆ.]

WOOD-CHICK. [SCOLOPACIDÆ.]

WOOD-LARK. [ALAUDINÆ.]

WOOD-LEOPARD. [ZEUZERA.]

WOOD-LOUSE. [ISOPODA.]

WOOD-PIGEON. [COLUMBIDÆ.]

WOOD-RUSH. [LUZULA.]

WOOD-SAGE. [TEUCHARUM.]

WOOD-SORREL. [OXALIS.]

WOOD-STRAWBERRY. [STRAWBERRY.]

WOOD-SWALLOW. [SWALLOW-TRIBE.]

WOOD-WARBLE. [SYLVIADÆ.]

WOOD-WREN. [SYLVIADÆ.]

WOOD-RUFF. [ASPERULA.]

WOODBINE. [LONICERA.]

WOODPECKERS. [PICIDÆ.]

WOODSIA, a genus of Ferns, having circular sori, with an inferior involucre, divided at the edges into numerous capillary segments.

W. ilvensis is one of the rarest of our British Ferns; it is found in only two localities in Europe, one in Wales, and one in Scotland. It takes root in the fissures of rocks and in the bleakest part of mountainous places. The fronds are elongated, the pinnae triangular, with deep lobes, the rhizoma tufted. There are varieties of this species, which are by some writers considered as distinct species, but Mr. Babington thinks this division unnecessary.

(Babington, *Manual of British Botany*; Newman, *British Ferns*.)

WOODY TISSUE. [TISSUES, VEGETABLE.]

WOOL. The curly hair of sheep and other animals is called Wool. [HAIR.]

WOOL COTTON. [GOSSYPIMUM; COTTON.]

WOOL-TREE. [ERIODENDRON.]

WOOLD. [RESEDACEÆ.]

WOORALY. [STRYCHNOS.]

WORBLER and WORNILS, common names given to the larva of the Bot-Fly. [BOTS.]

WORM-GRASS. [SPIGELIA.]

WORMS. [ANNELIDA; ENTOMOA; INTESTINA; VERMES.]

WORMSEED. [SPIGELIA.]

WORMWOOD. [ARTEMISIA.]

WORTHITE, a Mineral, occurring in rolled masses, having a foliated crystalline structure, and sometimes presenting very small apparently 4-sided prisms or plates. Colour white. Hardness 8.5. Lustre vitreous. Translucent. Specific gravity 3.1. Found near St. Petersburg, and on the shores of the Bay of Finland. Analysis, by Dr. Hess: Silica, 40.79; alumina, 53.06; magnesia, 0.88; water, 4.63.

WOUND-WORT. [STACHYS.]

WOW-WOW. [HYLOBATES.]

WRASSE. [CRENILABRUS; LABRIDÆ.]

WREN. [TROGLODYTINÆ.]

WRIGHTIA, a genus of Plants belonging to the natural order *Apocynaceæ*, named after Dr. William Wright. It has a 5-parted calyx, a salver-shaped corolla with the throat crowned by ten divided scales; the stamens exserted, attached to the throat of the corolla, and the anthers sagittal, cohering by their middle to the stigma; the ovaries two, cohering; the style single, filiform, dilated at top; scales five to ten in number, seated at the base of the calyx outside the corolla; the follicles distinct or combined with adnate placentas.

W. antidysenterica is a native of Ceylon, and has sweet-scented flowers with a form resembling those of the Jasmine. The wood is white, of a fine grain, and susceptible of polish, and is used by the turner and cabinet-maker. The bark of this shrub, which goes by the name of Conessi bark in Great Britain, and Palapatta in India, is asserted to be a specific in dysentery and of use in most disordered states of the bowels. Its milky juice is also used as a vulnerary.

WRYNECK. [YUNX.]

WYCH-ELM. [ULMUS.]

WYCH-HAZEL. [HAMAMELIDACEÆ.]

WYDLERIA, a genus of Plants belonging to the natural order *Umbellifereæ*, named after H. Wydier, a botanist.

X

XALLE, the Turkish name of the seeds of the Prickly Christ's Thorn, *Paliurus aculeatus*. [PALIURUS.]

XANTHIDIUM. [DESMIDIZÆ; INFUSORIA.]

XANTHITE. [IODOCRASE.]

XANTHIUM, a genus of Plants mostly referred to the natural order *Compositæ*, but of which Link forms a small order called *Ambrosiaceæ*. The genus *Xanthium* has monocious flowers; the male flowers have a many-leaved involucre, tubular petals, and a paleaceous receptacle; the female flowers have an involucre with a single leaf, which is bilocular, and embraces two flowers without petals. The species are herbs.

X. strumarium, the Lesser Burdock of English botanists, is a naked plant, with the lower leaves cordate, 3-lobed, toothed, and 3-nerved. It is found on roadsides and in cultivated places in Great Britain and other parts of Europe. *X. spinosum* is found in the south of Europe. It has entire or 3-lobed leaves, and is covered with 3-forked spines. An infusion of this plant is sometimes used as a yellow dye; hence the generic name, from *χρῆος*, yellow.

(Koch, *Flora Germanica*; Burnett, *Outlines*.)

XANTHO (Leach), a genus of *Brachyurous Crustacea*, placed by M.

Milne-Edwards among his *Canceriens Arquéus* [PLATYCARCINUS], between the genera *Lagostoma* and *Chlorodius*. The carapace is very wide, but never regularly ovoid, and with but little convexity; its surface generally entirely horizontal transversely, and not curved in its longitudinal direction, except on the anterior portion. Front ordinarily advanced, lamellar, and nearly horizontal; a narrow fissure divides it into two lobes, the border of which is more or less notched in the middle. The orbits present nothing remarkable, and resemble those of the Crabs and of *Zozymus*. The antennary fossets are narrow, transversal, and separated by a delicate partition. The basillary joint of the external antennæ is placed as in the *Zozymi*, but is in general shorter. The species are numerous, and spread in all seas.

We illustrate the genus by *X. floridus*, which is common on the English and French coasts, about two inches in length, of a reddish brown-colour, with black claws. (See next page.)

XANTHOCHYMUS, a genus of Plants belonging to the natural order *Guttifereæ*. It is by some botanists referred to the genus *Stalagmitis* [STALAGMITIS], from which it differs in its hermaphrodite flowers, and its stamens being disposed in five bundles. Three species of East Indian plants have been described under *Xanthochymus* by Dr. Rox.

*Xantho floridus.*

a, external jaw-foot; b, external antenna.

burgh. Of these the *X. pictorius* is the most important. This plant is the *X. tinctorius* of Linnæus. It has lanceolate acuminate leaves, wrinkled petioles, and fruit 1-4-seeded. It is a native of the East Indies, in valleys among the Circar Mountains.

XANTHOMYZA, called by Swainson *Zanthomiza*, is a sub-genus of

*Xanthomyza phrygia.* (Gould.)

Meliphaga. [MELIPHAGIDÆ.] The bill is moderate, much curved; the culmen considerably arched. Face naked. Middle toe much longer than the hallux. The tenuirostral type. (Sw.)

X. phrygia is the *Merops phrygius*, Black and Yellow Bee-Eater, and Black and Yellow Honey-Eater of Latham; Embroidered Bee-Eater of Shaw; Warty-Faced Honey-Eater and *Meliphaga phrygia* of Lewin; Le Merle Écaillé of Le Vaillant; *Philedon* of Temminck; *Philemon phrygius* of Vieillot; *Anthochera phrygia* of Vigors and Horsfield; and Mock Regent Bird of the colonists of New South Wales.

Sexes nearly alike in colouring, but the female much smaller than the male. The young destitute of the warty excrescences on the face, that part being partially clothed with feathers. It is a native of Australia.

XANTHOPHYLL. When Chlorophyll loses its green colour in autumn, it has been supposed that a new principle, Xanthophyll, takes its place. [CHLOROPHYLL.]

XANTHOPHYLLITE. [CLINTONITE.]

XANTHORHIZA, a genus of Plants belonging to the natural order *Ranunculaceæ* and the tribe *Pæoniæ*. It has a calyx composed of 5 deciduous sepals; 5 petals; 2- to 3-seeded carpels, but the seeds are usually solitary from abortion. There is but one species of this genus, *X. apifolia*, which is a small shrub, a native of North America from Virginia to Georgia, where it grows on the shady banks of rivers, and is commonly known by the name of Yellow-Root. The bark of the root is intensely bitter, and is used in America as a tonic, but the plant has also acrid properties.

XANTHORNUS, a genus of Birds described in the article STURNIDÆ. We subjoin a representation of the Baltimore Oriole, or Golden Robin, which belongs to this genus.

Baltimore Oriole.

XANTHOXYLACEÆ, *Xanthoxyls*, a natural order of Exogenous Plants. The flowers are unisexual and regular; the calyx in three, four, or five divisions; the petals usually of the same number as the divisions of the calyx, usually longer than the calyx, and sometimes absent; the aestivation is generally twisted and convolute; the stamens are equal in number to the petals, or twice the number, and arise from around the base of the stalk of the abortive carpels; in the female flowers they are either absent or very imperfect; the ovary is made up of the same number of carpels as there are petals, or of a smaller number; the carpels are either distinct or more or less combined; there are mostly two ovules in each cell, sometimes four; the styles are more or less combined, according to the cohesion of the carpels; the fruit is either membranous or in the form of a berry, sometimes having from 2 to 5 cells, and sometimes consisting of several drupes or 2-valved capsules, of which the sarcocarp is fleshy, and is easily separated from the endocarp; the seeds are

solitary or twin, pendulous, usually smooth and shining with a testaceous integument; the embryo lies in the midst of a fleshy albumen, radicle superior, and the cotyledons ovate or flat. The species of plants belonging to this order are trees or shrubs, with exstipulate, alternate, or opposite leaves furnished with pellucid dots. The flowers are either axillary or terminal, and coloured gray, green, or pink.

Xanthoxylum pterota.

1, branch with leaves, flowers, and fruit; 2, flowers separated; 3, male flower; 4, stalked capsules; 5, female flower; 6, section of seed.

The plants in this order were included originally by Jussieu in his *Terebinthaceæ*. They were first separated by Martius and Nees under the order *Xanthoxyleæ*, which was subsequently adopted by Adrien de Jussieu.

The species of *Xanthoxylaceæ* are found chiefly in America, especially in the tropical parts. A few of the species are found in Africa, in Mauritius and Madagascar, in India and China. One only is a native of Australia.

All this order, to a greater or less extent, possess aromatic and pungent properties. The species which are best known and used on account of these properties belong to the genera *Xanthoxylum*, *Brucea*, *Ptelea*, *Toddalia*, and *Ailanthus*. [BRUCEÆ; TODDALIÆ.]

Xanthoxylum fraxineum is a tree attaining a height of 14 or 15 feet, and is an inhabitant of North America from Canada to Virginia. The bark of this tree and its capsular fruit have a hot acrid taste, and are much used as a remedy for the toothache: it is on this account called Toothache-Tree, and this name is now applied to all the species of *Xanthoxylum*. A tincture of the bark is recommended as a remedy in rheumatism.

X. hyemale is a native of Brazil, where it is called Coentrilho, and the natives make use of a powder of the bark for the earache. The wood is also good and useful for many purposes.

X. Budrunga is a native of the East Indies, in Silhet, and is called Budrung; and the natives use the seeds, which have a warm spicy flavour, medicinally. The fruit is about the size of a pea, and the outer coat contains an exceedingly fragrant balsam.

X. Rhetsa is a native of the mountainous parts of the coast of the East Indies, and in the Telinga language is called Rhetsa-Maun, which means Council-Tree, as it is under the branches of this tree that the hill people assemble to discuss all matters of public interest.

X. emarginatum is a native of Cuba and Jamaica. It is a tree about 20 feet in height, with the branches inclining to the ground. On burning the wood of this tree the smoke is exceedingly odoriferous, and is supposed to have been the origin of the fine scent which Columbus perceived before discovering the island of Cuba.

The capsules and seeds of *X. hostile*, called Tej-hul by the natives, are used in India for intoxicating fish, and are supposed to be the Fagbreh of Avicenna. In Japan the capsules of *X. piperitum* are used as a substitute for pepper. The fruits of many of the species are also held to be antidotes to the action of poisons on the system, and there can be little doubt that the secretions of these plants would be found valuable stimulant remedies in many diseases.

The *Ptelea trifoliata* is a native of North America, and the young green shoots are used in infusion as an anthelmintic.

The species of *Ailanthus* are large trees, and their timber is used for various purposes in the countries in which they grow. *A. glandulosa* is a native of China and the Moluccæ, where it is called Ailanto. It attains a height of 60 feet. When the bark is wounded it gives out a resinous juice, which hardens in a few days. The wood is hard and heavy, and is susceptible of a very fine polish. It grows well in England. *A. Malabarica* is a large tree, a native of Malabar. The wood is used for making sheaths for spears, &c. A resinous juice flows from the bark when wounded. The fruit is triturated with maize and mixed with rice in decoction, and used as an application in ophthalmia.

XANTHOXYLUM. [XANTHOXYLACEÆ.]

XANTHUS. [PSEUDOCARCINUS.]

XEMA. [LARIDÆ.]

XENOPELTIS, Reinwardt's name for a genus of Serpents which have two great triangular and imbricated plates behind the eyes, so that they are confounded with the scales which succeed them, and which above become smaller. The form belongs to the great group of *Coluber*.

XENOPS, Illiger, a genus of Birds, placed by Mr. Swainson in his family *Certhiada*, as the last genus of his sub-family *Certhiina*.

X. genibarbis may be regarded as an example. It is a native of Brazil.

Mr. Swainson remarks that this extraordinary and not inelegant little creature has a bill totally different from that of any other bird. Its general habit, he states, evinces a close connection with the *Sitta*, particularly those of Australia, some of which have their bills (which are slender) slightly inclining upwards, thus forming a connection between *Xenops* and the Straight-Billed *Sitta* of the Old World.

Xenops genibarbis. (Swainson.)

XENOTINE, a Mineral occurring crystallised. Primary form a right square prism. Cleavage lateral, perfect. Colour yellowish-brown; streak pale brown. Fracture uneven and splintery. Hardness 4.25 to 5.0. Lustre resinous. Opaque. It is found at Lindsnes, in Norway. Its analysis, by Berzelius, gives—

Phosphoric Acid	33.49
Yttria	62.58
Subphosphate of Iron	3.93

—100

XIPHIAS. [SCOMBRIDÆ.]

XIPHOSOMA, Fitzinger's name for a genus of Serpents. [BOIDÆ.]

XIPHOSURA. [LIMULUS.]

XIPHOSURUS. [IGUANIDÆ.]

XIPOTHECA, a genus of Fishes belonging to the family *Tetrinoides*. [TETRINOIDES.]

XULIONOSPIONITES, a Fossil Fruit.

XYLITE. [IRON.]

XYLOCARPUS (from *ξύλον*, wood, and *καρπός*, fruit), a genus of Plants belonging to the natural order *Meliaceæ*. This genus, with *Persoonia*, has been referred by Aublet and other botanists to the genus *Carapa*. [CARAPA.]

XYLOCOPIA (*Wood-Cutters*), a genus of Insects of the sub-family *Scopulipides*, Latreille, or *Anthophorides*. The insects composing it are characterised by the very thick coating of hairs upon the hind legs of the females, which constitute pollen-brushes. The basal joint of the posterior tarsi usually exhibits its extremity angularly produced. They have no pollen-plates, and the abdomen is destitute of a ventral pollen-brush. The wings have usually three perfect sub-marginal cells; the third joint of the antennæ is frequently long and elevate, being very slender at the base; the mouth is sometimes considerably developed. Notwithstanding the shortness of the wings and the comparative bulk of the body, these insects fly with much strength and activity, and with a loud buzzing noise.

The sexes differ considerably (in many cases), both in colour and structure; the males in some cases having very long antennæ, while in others the posterior femora are much thickened, and in a few the tarsi of the intermediate legs are furnished with curious brushes of hair. The face is frequently of a pale yellow-colour. The females are usually of darker and more obscure colours than the males. They form their nests in crevices of old walls or in banks exposed to the sun. Their cells are composed of earth and are very smooth in the inside, and the mouth of the nest is closed with the same material.

The wings of the *Xylocopa*, or (as they are frequently termed) Carpenter-Bees, are most frequently (although not always) black, with a fine purple or violet gloss. The habits, &c. of a French species, the *X. violacea*, have been carefully studied. The females of this species appear in the spring, and select posts, palings, &c. in which they construct burrows from 12 to 15 inches in length, and rather more than half an inch in diameter. The two extremities of the tunnel are covered, leaving a narrow passage at each end. Upon the completion of these works, they deposit an egg at the bottom, with a due supply of pollen-paste; the whole is then covered with a layer of agglutinated sawdust, formed during the construction of the burrow. The layer thus formed is made to act in the double capacity of a roof for the original cell and a floor for another above it. In this manner about twelve cells are usually formed. When the larvæ are full grown, they assume the pupa state, head downwards, so as to allow the lowermost and oldest to make its way out of the bottom of the burrow as soon as its wings are sufficiently developed, and which consequently occurs sooner than in those in the upper cells.

The males of some of the larger species, *X. latipes*, and some others not yet properly described, have the fore-legs greatly dilated. An excellent history of the *Xylocopa* is given by Réaumur ('Mém.,' tom. vi., mém. iv.).

XYLOMA, a genus of *Fungi* approaching in character *Sphaeria*. From this genus it was formerly distinguished by negative characters, such as the sporidia not being external. All the species which were referred to this genus are placed by Berkeley under the genera *Sphaeria*, *Hysterium*, *Phacidium*, &c. The most common species of this genus are found on the decaying leaves of trees, especially of the sycamore and maple, the leaves of which are frequently covered with black spots, the results of the attacks of *Fungi* formerly referred to this genus.

XYLOMELON, or **XYLOMELUM**. [PROTEACEÆ.]

XYLOPHAGA. [PHOLADIDÆ.]

XYLOPHAGI (*Wood-Eaters*), a family of Insects of the order *Coleoptera Tetramera*: they are distinguished from the family which usually precedes them (the Weevils) by the absence of a proboscis. [CURCULIO.] The antennæ are thickened towards their extremities, or perfoliated from the base; always short, and usually composed of less than eleven joints. The tarsi, which in some cases appear to be 5-jointed, are usually entire, the penultimate joint being dilated in some species and cordiform in others. In the latter case the antennæ are always terminated by a club, either solid and ovoid or trifoliate, and the palpi are short and conical. These insects generally live in wood, which is perforated and channelled in various directions by their larvæ. Some species are destructive to pines and firs, some to olives, while others feed on *Fungi*.

This family is divisible into three sections.

Section I. Those which have the antennæ composed of ten joints at least, either terminated in a thick club, generally solid, or having three elongated plates, or forming a cylindrical and perfoliate club from the base; the palpi are conical; the anterior tibiae in the majority are toothed and armed with a strong hook, and the tarsi generally have the penultimate joint bi-lobed. Some have the palpi very short, and the antennæ terminated in a solid or trilamellar mass, preceded by five joints at the least.

These *Xylophagi* compose the genus *Scolytus*, Geoffroy.

In some the penultimate tarsal joint is bi-lobed, and the antennæ have seven or eight joints preceding the club. *Scolytus* proper (*Eccoptogaster*, Herbst) has the antennæ straight and naked, the club solid and very compressed, its annuli forming concentric constrictions. *S. destructor* (*Hylesinus Scolytus*), the Common Elm-Destroying Scolytus, commits great ravages in the neighbourhood of London. This insect does not appear to restrict itself to the elm, but has also been found

upon the plum. Dr. Hammerschmidt, who has frequently observed them in the bark of this tree (in the neighbourhood of Vienna), considers however that it differs slightly from the *S. destructor*, and terms it *S. Pruni*. Except in being smaller, there appears no other distinction.

The perfect insect or beetle is only two lines long, and the majority of them are still smaller; its breadth is about half a line, and it is firm and resisting to the touch. The head and thorax form the principal part of the body; they are black and shining, very finely and thickly dotted, and the former (the head) covered with short yellowish gray hairs. The antennæ are of a light pitch-brown, ending in a knob. The wing-cases are obliquely cut off behind, and at the base near the thorax somewhat hollowed: they are marked in dotted lines, and their colours pitch-brown. The abdomen from the base to the apex appears as if elastically cut off, and is of a similar colour to the thorax and dotted. The legs are of a reddish-brown, and the tibia dilated. The larva is of a yellowish white, and has a relatively large yellow shining head and a brown mouth. It is from one to two lines long, and it exhibits a whitish transparent swelling between the head and the first ring on the thorax, which appears to be characteristic of the larva of this species. They confine themselves to the inner bark, forming winding and convoluted paths in it. Much important matter upon the habits and economy of the elm-destroying *Scolytus* will be found in the communication of Audouin and Spence upon this subject, to the respective Entomological Societies of Paris and London.

Hylesinus, Fabr., has the club of the antennæ solid and annulated, but pointed at the tip.

Hylurgus, Latreille, has the club of the antennæ solid, globular, and annulated. *Hylurgus* (*Hylesinus*) *piniperda*, the Scotch-Pine Black Beetle, is somewhat ehaggy and black; the wing-cases are pitch-black, irregularly striated and entire at the tips; thorax anteriorly narrowed; antennæ and feet brownish red. The larvæ is thick, cylindrical, milk-white on the middle of the body; the head dull yellow, as also the front of the body and the anal extremity, only somewhat of a lighter tint. The abode and place of propagation of the perfect insect are in the pith of the side-twigs of the pine.

According to Bechstein, it bores through shoots of the spruce-fir when there are none of the Scotch pine to be had. The eggs are laid under the bark of sickly and felled pines, in the bark of which the maggot resides, while it feeds on the stagnated fermented juice which is found under the bark. The larvæ feed on the trunks of dead or dying trees, and the beetle only places her brood on healthy trees when compelled by necessity to do so. In one respect the ravages of this insect do less injury than those of some others, inasmuch as it generally only attacks the side-twigs, leaving the leading shoot untouched.

Campocerus, Dej. [CAMPTOCERUS.]

Phloeotubus, Latr., differs from all the rest in the club of the antennæ being formed of three long filaments.

In others the tarsal joints, apparently five in number, are entire, and the club of the antennæ commences at the sixth or seventh joint.

Tomiscus, Latr., has no notches at the sides of the thorax, and the tibiae are not striated.

Platypus, Herbst, has the sides of the thorax notched to receive the femora, and the tibiae are transversely striated. Fossil specimens of this genus have been found embedded in amber.

The others have the palpi large, very visible, and of unequal length; body depressed and narrowed anteriorly; the antennæ either 2-jointed (the second joint being very large and irregularly shaped), or 10-jointed and entirely perfoliated; tarsi entire.

These insects are of great rarity and very singular appearance, and are also foreign to Europe. They compose the genus *Pausus*, Linn.

Pausus proper has only two joints to the antennæ, the second very large and compressed.

P. sphaerocerus. Professor Afzelius observed a dim phosphoric light to be emitted from the singular hollow antennæ of this insect. ('Linn. Trans.,' iv., 261.)

Hylotorus, Dalm., composed of a single species, apparently with ocelli, and with the antennæ scarcely longer than the head, and 2-jointed.

Cerapterus, Swed., has the antennæ 10-jointed and perfoliated. (Westwood in 'Trans. Linn. Soc.')

Section II.—Those which have only 10-jointed antennæ, and the maxillary palpi do not taper to a point, but are either of equal thickness throughout or dilated at the extremity. The joints of the tarsi always entire.

They are divisible into two principal genera, according to the mode in which the antennæ terminate. The three terminal joints form a perfoliate club in the first, or *Bostrichus*, Geoff.

Bostrichus proper has the body more or less cylindrical; the head rounded, nearly globular, and capable of being received into the thorax as far as the eyes; the thorax is never less convex before, and forms a kind of hood. The first two joints of the tarsi, as well as the last, are elongated. The species are found in old wood and timber.

B. dispar (*Apate dispar*, Fabr.), *Xyloterus dispar*, Erichson. This Apple-Bark Beetle is very common in Austria, but rare in this country. It is termed *dispar* because the male is not only about half the size of, but differently formed from, the female, bearing more resemblance to *Anisoplia horticola* than to the bark-beetles generally. The head and

thorax are black; the extremity of the palpi and antennæ reddish; the wing-cases long, blackish, and somewhat hairy; the feet dilated, and of a reddish-yellow; the thighs black. The female somewhat resembles the Long-Haired Bark-Beetle, (*B. villosus*), but the wing-cases are not deeply furrowed, and the spots not so deep as they are in that species. The male (as we have previously observed) is smaller than the female, and it has chestnut-brown wing-cases and reddish thighs. These insects restrict their attacks almost entirely to the apple-tree. They make no distinction between the age or healthy state of the tree, whether it is young or old, or whether it may shoot out much or little; all that they require is that it should not be of a less thickness than about half an inch in diameter. Having found a suitable place, the female bores a completely round but somewhat oblique hole, penetrating nearly to the centre of the tree; she first goes upwards to the side, and then downwards. Upon coming near the bark, she turns back, and goes to the other side or downwards, forming a new path. These paths, leading upwards and downwards, seldom exceed one inch and a half in length. The minute particles of wood, or wormmeal, which are ejected, indicate the presence of the insect. In the case of the Pine-Beetle (*B. typographus* and *B. piniperda*), it is stated by Bechstein to be ejected by the larvæ, but in this case it is thrown out by the beetle itself.

B. typographicus, the Typographer Bark-Beetle, is perhaps the most destructive of the whole class. It particularly attacks the silver-firs (*Picea pectinata*); but when that tree is not abundant, it will attach itself to other species of pines and firs. The perfect beetle is from two to two and a half lines long, and from one line to one line and a quarter broad, and hairy. As long as it remains under the bark, it is of rusty yellow; but on exposure to the air, changes to a brownish-black colour.

The injury this insect does is chiefly effected by the larvæ, which destroy the sap-wood; and thus, if they are numerous, can kill a healthy fir in the course of a few weeks.

B. orthographus, Duftsch., the Spruce-Fir Bark-Beetle; *B. laricis*, Fabr., the Larch-Bark Beetle; *B. pinastri*, Bechst., Red Bark-Beetle, require no particular notice.

Proa, Fabr., has the body narrower than *Bostrichus*, and the thorax flat.

Cia, Latr., has the body oval, depressed, or but little elevated; last tarsal joint much longer than the others; head of the males frequently horned. Many minute species are found on *Fungi*.

Nemotoma, Deesmar., has the body long, linear, and the mandibles robust and exerted. *N. elongata* is a small and rare British species, sometimes found under the bark of old palings.

The second genus is distinguished from the first by having the club or tenth joint of the antennæ solid and button-shaped; the body is elongated, with the front of the head narrowed into an obtuse snout or muzzle; the palpi are very small, and, as well as the mandibles, not prominent.

This genus is termed *Monotoma*.

Monotoma proper, Herbst, has the head as large as the thorax, and separated from it by a narrower part.

Cerylon, Latr., has the front of the head produced into an obtuse triangle, the first joint of the antennæ much longer than the second; the body nearly oval or paralleloiped, and the elytra not truncate behind.

The genera *Synchita*, Helw., *Rhyzophagus*, Herbst, &c., are included in *Monotoma*, but are not deserving of any especial remarks.

Section III.—The *Xylophagi* of this division have eleven distinct joints in the antennæ; the palpi filiform, or thickened at the tips in some, or slender at the tips in others; the tarsal joints entire. Those in which the club of the antennæ consists only of two joints constitute the genus *Lyctus*.

Lyctus proper, Fabr., has the mandibles and basal joints of the antennæ exposed. *Diodesma*, Megerle, and *Bitoma*, Herbst, are included in the genus *Lyctus*.

In some the mandibles are concealed or scarcely visible. These are the genus *Mycetophagus*.

Mycetophagus proper has the antennæ at least as long as the thorax; body oval; thorax transverse; and the club of the antennæ commencing at the sixth or seventh joint.

Silvanus has the body nearly linear, of greater length than breadth, and as broad as the base of the elytra; palpi nearly filiform. *S. dentatus*, a small flat insect, frequently found floating in tea and coffee, being introduced with the sugar.

In others the mandibles are entirely exposed and large; the body often narrowed and depressed. These insects constitute the genus *Trogosita*, Olivier.

Trogosita proper has the antennæ shorter than the thorax; the mandibles shorter than the head, and crossed; the labium almost square, and not prolonged between the palpi, and the maxillæ have but a single lobe.

T. mauritanica, Linn., a flat Beetle, 4 lines long, of a pitch-black colour, found in nuts, bread, and the bark of trees: its larva is known in Provence under the name of Cadelle, and is said to commit great devastation on grain.

Protomis, Latr. (*Megagnalus*, Meg.), and *Passandia*, Dalm., belong to this genus.

The reader who has carefully followed us over the three sections of the *Xylophagi* will readily perceive that Latreille makes use of this group for the purpose of effecting a transition between the *Curculionida* and *Cerambycida*, commencing with those which have the club of the antennæ solid, and proceeding through those families in which the club is less compactly constructed, as far as the *Trogosita*. In this single character the transition is certainly obvious enough; but in other and more important points, as for instance in the structure of the imago, as well as in that of the larva, it cannot be maintained; and Westwood is probably right in transferring many of the *Xylophagi*, especially the *Trogositana*, to the *Necrophaga*.

XYLOPHILI (*Wood-Lovers*), a section of Insects of the genus *Scarabæus* (Linn.), comprising two divisions, corresponding with the families *Dynastidae* and *Rutelidae* of M'Leay.

The *Dynastidae* (comprising the *Geotrupes* of Fabricius) constitute an extensive series of gigantic insects, the males of which are pre-eminently distinguished by various singular protuberances, horns, or tubercles arising from the head and thorax, and often from both those parts (occasionally giving the insect a very peculiar appearance), and of which the females are destitute. The clypeus is small, triangular, pointed in front, or terminated by two small obtuse teeth; the labrum is a broad membranous plate, entirely concealed by the clypeus; the jaws are very robust and horny, and furnished with one or two obtuse teeth. The maxillæ are either terminated by a coriaceous ciliated lobe, or by an elongated corneous piece, having one or several acute teeth on its inside; the mentum is large, concealing the labrum, and of an ovoid or triangular form, truncated in front; the prosternum is not produced behind into a lobe; the tarsal claws are of an equal size, and the scutellum is distinct; the elytra do not entirely cover the extremity of the abdomen; the antennæ are 10-jointed, with the club 3-jointed, the central lamellæ not being inclosed within the two external ones. [DYNASTES.]

The colour of these insects is usually of a dark rich brown or chestnut colour. They reside either in rich vegetable mould or in the putrid detritus arising from the decomposition of trees.

Oryctes, Illiger, is a very numerous genus, having the legs all nearly of the same length, with the four hind tibia thick and crooked. As a type of this genus, we may take the common continental species, *O. nasicornis*, which is frequently found in the larva state in tan-pits. The eggs are oblong, about the size of a grain of hemp-seed, and of a yellow colour; the larva continues in that state four or five years, and then incloses itself in an oval and very smooth cocoon; the pupa lies upon its back, and the imago remains in its cell for about a month after it has attained the perfect state. The insect is about an inch and a half long, and the male is distinguished by having a curved horn upon the head.

Some of the *Dynastidae* acquire an immense size. The *Scarabæus Hercules* (Linn.), an inhabitant of South America, is 5 inches long.

The *Dynastidae* chiefly occur in the tropical zone, there being only 6 or 8 species found in Europe.

According to M'Leay, the proportion of tropical to extra-tropical species may be estimated at about eight to one.

The *Rutelidae* consist entirely of exotic and for the most part brilliantly-coloured insects, of a moderate size, having the body of an ovate, subconvex, or depressed form, and shorter and more rounded than in the previous family, from which they also differ in the absence of the peculiar horns or promiunces which are present on the heads of the male *Dynastidae*. The antennæ are 10-jointed, the club 3-jointed; the labrum is exerted with the anterior margin coriaceous; the mandibles are short and horny, and more or less exerted with a notch on the outer margin near the tip; the maxillæ are also horny and truncated, and with four or six strong teeth at the tip, with the inside sometimes membranous; the labrum is concealed by the mentum; the elytra do not conceal the extremity of the abdomen; the thorax is transverse-quadrate; the scutellum large and distinct; the mesosternum is anteriorly produced between the base of the middle legs; the legs are robust, with the posterior femora sometimes greatly thickened; the claws of the tarsi are generally unequal in size, and occasionally divided; the clypeus commonly exhibits a transverse section, dividing as it were into two parts before the eyes. (Westwood.) The head and thorax are identical in both sexes.

With a few exceptions, the *Rutelidae* are confined to the equatorial regions of America.

Herodon, Oliv., composed of two African species, *Cyclocephala*, Latr. (*Chalepas*, M'Leay), *Rutela*, Latr., *Pelidnota*, M'Leay (*Ophognathus*, King), *Macraspis*, M'Leay, *Chasmodia*, M'Leay, *Omdis*, Latr., &c., belong to this family.

Two of the most remarkable species are the *Chrysophora chrysocolora* [CHRYSOPIORA], and the *Scarabæus Macropus*, which was depicted long since by Francillon under the name of the Kangaroo-Beetle.

XYLOPHYLLA, a genus of Plants belonging to the natural order *Euphorbiaceæ*. The species of this genus are shrubs, with a hard and rigid foliole. They are natives of the West Indies, where they are known by the name of Sea-Side Laurels and Love-Flowers.

XYLOPIA, a genus of Plants belonging to the natural order *Anonaceæ*. It has a 3-5-lobed calyx, with ovate coriaceous acutish segments; 6 petals, of which the 3 outer ones are largest; numerous

stamens inserted into a globose receptacle; from 2 to 15 carpels on short stipes, flattened, 1-celled, 1-2-seeded, sometimes dehiscent, sometimes baccate; the seeds obovate, shining, furnished with an aril. About twelve species of this genus have been described, all of them natives of South America. They are trees or shrubs, with oblong or lanceolate leaves, and axillary, bracteate, 1- or many-flowered peduncles. The wood of all is bitter, hence they are called Bitter-Woods.

X. frutescens, Shrubby Bitter-Wood, is a native of Brazil and Guyana. The leaves and wood are aromatic. The seeds also contain an acid aromatic oil, and are used in Guyana by the negroes as a substitute for pepper.

X. glabra is a native of the islands of Barbadoes and Jamaica. The wood, bark, and berries have an aromatic bitter taste resembling that of the orange seed. Pigeons feed on the berries, and the flesh of these birds is improved in flavour during the season they eat this fruit. When fresh gathered from the tree the berries have an agreeable flavour, and may be eaten with impunity. The wood readily communicates its bitter flavour. Sugar sent to this country in hogheads made of it could not be sold on account of the bitter flavour it had acquired. Articles of furniture made of it are proof against the attacks of insects. Persons who work the wood complain of the bitter taste which it produces in their mouths from the dust.

X. sericea is a native of Brazil. It is called in Brazil Páo d. Embeira and Pindaíba. The bark is fibrous and tough, and is used for making cordage and cables. The fruit is highly aromatic, with the flavour of pepper, for which it might be advantageously substituted. Most of the other species possess the toughness of the bark and the aromatic properties of the fruit.

XYLOTOMA. [LEPTIDES.]

XYPHOSOMA. [BOIDE.]

XYRICHTHYS, a genus of Fishes allied to the *Labrus*, or Wrasse, which the species resemble in general form, but are much compressed and have the head suddenly truncate in front. Their bodies are covered by large scales, but their hands are usually naked. A species which is esteemed as an article of food inhabits the Mediterranean.

XYRIDA'CEÆ, *Xyridæ*, a natural order of Endogenous Plants. The species are herbaceous plants with fibrous roots. The leaves are radical, sword-shaped, scarious, dilated and equitant at the base. The flowers are arranged in terminal naked imbricated heads; the calyx is glumaceous, 3-leaved; the corolla petaloid, coloured, with 3 petals; the stamens 6; 3 fertile, inserted upon the claws of the petals; 3 sterile, alternate with the petals; the anthers 2-celled, and turned outwards; the ovary single, the style bifid; the stigmas multifid or undivided; the capsule 1-celled, 3-valved, many-seeded, with parietal placentæ; the seed with the embryo on the outside of the albumen, and at the end most remote from the hilum.

As at present constituted this order comprises only the genera *Xyris* and *Abolboda*. The species of these genera are found generally in the hotter parts of the world, chiefly in the tropics of America, Asia, and Africa. Some of the species of *Xyris* are found in the southern states

of North America. *X. Indica* is said by Agardh to be used as a remedy in itch and leprosy.

Xyris operculata.

a, an entire plant; b, heads of flowers; c, flower separated; d, fruit; e, the lower part of the pericarp.

XYRIDALES. [ENDOGENS.]

Y

YAK. [BOVIDÆ.]

YAM. [DIOSCOREA.]

YAPOCK. [MARSUPIATA.]

YARR. [SPERGULA.]

YARROW. [ACHILLEA.]

YEAST, a substance found on the surface of fermenting liquids, and when removed capable of producing fermentation in other liquids susceptible of this action. On placing Yeast under the microscope it presents a number of cells immersed in a mass of amorphous matter. The cells are sometimes single, and at other times several are united together in a kind of chain. These cells are supposed to partake of a fungoid character, and they have been called the Yeast-Fungus, or Ferment-Cells. A genus and species have been constituted for the reception of this organism, under the name of *Saccharomyces Cerevisia*.

This plant has been supposed to be the active cause of fermentation, and the carbonic acid given off during that process has been regarded as the result of the growth of the plant. This seems to be a misinterpretation of the phenomena, as the plant is probably the result of the carbonic acid given off during the process of fermentation rather than its cause. Schleiden supposes that these ferment-cells originate in liquids, independently of other cells, and are truly instances of the formation of cells in a free fluid. He observes however that they have no power of reproducing other cells. The whole subject of the nature of these cells, their mode of production, and the history of their development, as well as the phenomena of fermentation in general, require further elucidation.

(Schleiden, *Principles of Scientific Botany*; *Micrographic Dictionary*, articles 'Fermentation,' 'Torula,' 'Yeast.')

YELLOWHAMMER, the common name for the *Emberiza citrinella*, Linn.

Pennant quotes the Bruant of Belon ('L'Histoire de la Nature

des Oyseaux,' p. 366) as this species, and the description seems to warrant the quotation. Belon considers the bird to be the 'Arbos of

Yellowhammer (*Emberiza citrinella*).

Aristotle ('Hist. Anim.' ix. 1), and remarks that the Greeks of his time did not call it by the ancient appellation in their tongue, but by the Latin name *Florus*, "car ila ont esté dominez par les Latins, dout ils ont retenu telle diction." It is the Bruant of the French generally; Serramolle and Zivolo di Testa Gialla of the Italians; and, according to the 'Portraits d'Oyseaux,' Hortolano, Cia, Megliarina, Verzerot, Paierizo, and Spairards of the same people. It appears to be the Groning and Golspink of the Swedes; Goldammer, Ammering, and Goldammering of the Germans; Geel-Gerst of the Netherlands; Yolt, Yellow-Yoldrin, Yellow-Yowley, and Yellow-Yeldrock of the English; and Llinos Felen of the Welsh.

These birds are caught and fattened for the table with the Ortolan in Italy, whence probably one of the Italian names above noticed.

YELLOW-WORT. [CHLORA.]

YENITE. [IRON.]

YEW. [TAXUS.]

YTTRIA. [YTTRIUM.]

YTTRIUM, a peculiar metal discovered in the state of oxide, or earth, and named *Yttria*; it was found by Gadolin in 1794 in a mineral from Ytterby in Roslagen, Sweden; this was at first called *Ytterbite*, and afterwards *Gadolinite*, by which name it is now generally known.

The minerals which contain Yttrium, or rather its oxide, *Yttria*, are as follows:—

Gadolinite occurs crystalline and massive. Primary form an oblique rhombic prism. Cleavage imperfect, so that its direction has not been ascertained. Fracture flat, conchoidal, sometimes splintery. Hardness 6.5 to 7.0. Colour greenish-black, very dark. Streak greenish-gray. Lustre vitreous, inclining to resinous. Opaque, translucent on the edges. Specific gravity 4.238.

The massive variety is amorphous, structure compact. Before the blow-pipe it decrepitate if not cautiously heated, and does not melt except in small splinters. If heated with precaution on charcoal it incandesces at once, and its colour becomes paler. In nitric acid it loses its colour, and gelatinises.

Gadolinite is found at Ytterby near Stockholm, and at other places in Sweden, and also in Greenland.

This mineral has been repeatedly analysed, and with somewhat varying results: thus, it was examined by Ekeberg, Klaproth, and Vauquelin, without the detection of oxide of cerium, which was found by Berzelius, who gives the following as the composition of the mineral from Broddbo:—

Silica	24.16
Yttria	45.93
Oxide of Cerium	16.90
Oxide of Iron	11.34
Moisture	0.60

In a specimen from Kararfvet, Berzelius found 2 per cent. of glucina, and rather more than 3 per cent. of lime. Other analysts have obtained a much larger portion of glucina. Scheerer has more lately detected 4.75 per cent. of oxide of lanthanum in the *Gadolinite* from Ilitterun.

Tankelite, Phosphate of Yttria, occurs crystallised and massive. Primary form a square prism. Cleavage parallel to the lateral faces of the primary crystal. Fracture uneven, splintery. Hardness 4.5 to 5. Colour yellowish-brown. Streak pale brown. Lustre resinous. Opaque. Translucent, in thin splinters. Specific gravity 4.557. Acids do not act upon this mineral. Before the blow-pipe infusible per se on charcoal. With borax dissolves slowly into a colourless glass. It yields no water when heated. It is found in Norway. It contains phosphoric acid, Yttria, and di-phosphate of iron.

Ytrocercite.—It occurs crystallised and massive. Primary form the cube. Fracture uneven. Hardness—scratches fluor-spar, and is scratched by quartz. Colour violet-blue, grayish-blue, grayish-red, and grayish-white. Opaque. Specific gravity 3.447.

Massive Varieties.—Structure granular, compact. Before the blow-pipe infusible, but loses its colour and becomes white. Acted upon by acids, and the solution gives a precipitate soluble in carbonate of ammonia. Found at Finbo and Broddbo in Sweden. It contains fluoric acid, yttria, oxide of cerium, and lime.

Columbate of Yttria. [FERGUSONITE.]

Titanate of Yttria. [POLYMIONITE.]

Ytrocolumbite; *Ytrotantalite*; *Yellow Ytrocolumbite*.—It presents no trace of crystallisation. It is found between felspar in the state of lamellæ, sometimes in grains not exceeding the size of a peppercorn. The longitudinal fracture of the lamellæ is foliated, the cross-fracture fine-grained. Lustre resinous on the surface, vitreous in the fracture. Colour yellowish-brown, accidentally with green spots or stripes. Streak white. Opaque. Scratches glass with difficulty, but is very distinctly scratched by it. Specific gravity 5.882.

Dark Ytrocolumbite occurs with the preceding, commonly in thin laminae, seldom in grains. Fracture conchoidal in one direction, fine-grained in another. Lustre intermediate between vitreous and resinous. Colour brownish-black. Streak white. Very small fragments are translucent, almost colourless, sometimes a little yellowish. Hardness equal to that of the preceding.

Black Ytrocolumbite.—Indistinct traces of crystallisation. Fracture

lamellar in one direction, coarse granular in another. Disseminated, seldom the size of a hazel-nut. Lustre imperfect metallic. Opaque. Colour black. Streak gray. Brittle. Scratches glass. Specific gravity 5.395. (Haidinger, 'Mineralogy,' vol. iii, p. 173.)

Analysis of the above by Berzelius:—

	a Yellow.	b Brown.	Black.
Columbic Acid	60.124	59.50	51.815
Tungstic Acid	1.044	1.25	2.592
Yttria	29.780	29.90	38.515
Lime	0.500	3.29	3.260
Oxide of Uranium	0.622	3.23	1.111
Oxide of Iron	1.155	2.72	0.555
	99.225	99.89	97.848
			95.75

Before the blow-pipe they are all infusible per se, but decrepitate and acquire a lighter colour. They are not acted upon by acids.

The above minerals all occur at Ytterby, and in the neighbourhood of Fahlun in Sweden. [PYROCHLORE.]

YTTRICERITE. [YTTRIUM.]

YTTRICOLUMBITE. [YTTRIUM.]

YTTRICILMENITE. [URANIUM.]

YTTRIC TANTALITE. [YTTRIUM.]

YUCCA, a genus of Plants belonging to the section *Asparagaceæ*, of the natural order *Liliaceæ*. The corolla is inferior, bell-shaped, its segments without nectaries; stamens club-shaped; style none; berry hexagonal, of six cells; seeds numerous, flat.

Y. gloriosa, Common Adam's-Needle, is a caulescent plant, with lanceolate straight furrowed leaves, their edges smooth and entire. This handsome plant is a native of Peru and North America. It grows on the shores of Carolina, where it blossoms in July and August, its panicle of elegant flowers attaining a height of 10 or 12 feet. In British gardens the stem of this plant does not attain a height of more than 2 or 3 feet.

Y. aloifolia, Aloe-Leaved Adam's-Needle, has linear-lanceolate even straight leaves, with the edges bordered by fine callous notches. This plant is a native of North and South America.

Y. draconis, Drooping-Leaved Adam's-Needle, and *Y. filamentosa*, Thready Adam's-Needle, are cultivated in this country. The latter grows in the open air, and blossoms in the autumn. Its flowers are panicle and pendulous, and of a cream-colour. The leaves have their edges beset with long recurved threads.

YUNX, a genus of Birds. The bill is short, straight, depressedly conical. Nostrils basal, naked, partly closed by a membrane.

Wrenneck (*Yunx torquilla*).

Tongue long, vermiform, with a horny point. Wings moderate, second quill longest. Tail-feathers flexible. Feet with two anterior toes joined together at their origin, and two behind unconnected.

Yunx torquilla. This is the *ΰνξ* of the Greeks. Aristotle has well described the bird, its long tongue, its power of protruding and retracting it, and the writhing snake-like motion which it can impart to its neck without moving the rest of the body. ('Hist. Anim.' ii. 12.) It has been made familiar to most of our literary readers by the adjuration in the second Idyll of Theocritus ('Pharmaceutria'). It is also the *Iynx* of the Romans. (Pliny, xl. 47.) *Yunx* is the form used by Linnæus and zoologists generally, but it ought to be *Iünx*, or *Iynx*. The Wryneck is the Torcol of the French, and also the Tercou, Torcou, Turcot, Tercot, and Torcot of the same, according to Belon; Torcicollo, Collartorto, Stortacoll, Capetorto, Vertilla, and Formicula, of the Italians; Gjökyta of the Swedes; Bende-Hals of Brunnich; Natterwindl, Wendhals, Wendehals, and Dre-Hals, of the Germans; Long-Tongue, Emmet-Hunter, Snake-Bird, Cuckoo's-Mate, Cuckoo-Maid, Cuckoo's-Maid, and Cuckoo-Fool (two last Gloucestershire) of the English; Gwas y Gôg and Gwddfdro of the Welsh; Arizui of the Japanese.

The male has the ground-colour of the plumage of the upper parts rusty ash-colour, irregularly spotted and speckled with brown and black; a large brown streak extends from the occiput to between the scapulars; on the external barbs of the wing-feathers rusty squared spots; tail-feathers bounded with black zig-zags; throat and front of the neck pale rusty, with small transverse black lines; bill and feet olive-brown; irides hazel or yellow-brown. Total length 7 inches. It is found in Denmark, Sweden (May), Germany, Holland (where it is rare), France, Spain, and Italy (summer); England, and Wales,

Scotland (rare in the last and in the north of the first—summer); Kamtschatka (Vieillot), Japan, Himalaya Mountains. Winter residences, North Africa and warm parts of Western Asia.

When the Cuckoo is heard, the Wryneck may be looked for; and from their advent and departure at about the same time, some of the English names and one of the Welsh appellations, Gwas y Gôg, must have originated, for in other respects there is no relationship or similarity between the birds.

Caterpillars and a variety of insects form the food of the Wryneck, and it is a great devourer of ants and their eggs. Elderberries have been mentioned as being a part of its diet.

Colonel Montagu says that the Wryneck makes a noise very like the smaller species of Hawks, frequently repeating it in spring. Mr. Yarrell describes the note as a sharp sound, repeated several times, and not unlike the whistle of a kestrel.

In captivity the Wryneck is a favourite, and the bird soon becomes reconciled to the half-reclaimed state in which English and French boys are fond of keeping it, taking it out to the woods with a long string tied to its leg, and suffering it to ascend trees and forage for food generally, within the length of its tether, and letting it climb at intervals about their dress.

In the 'Portraits d'Oyseaux' the following quatrain is printed under the cut of this species:—

"Le Tercot est au pic verd ressemblant,
Do naturel et non de corpulence,
Sa langue longue hors de trois doigts il lance,
Ayant en ce du serpent le semblant."

The two last lines are very nearly a translation from Aristotle.

Z

ZAMIA, a genus of Plants belonging to the natural order *Cycadaceæ*. The species of this genus are trees with a single cylindrical trunk, increasing by the development of a single terminal bud, and covered by the scaly bases of the leaves; the wood consists of concentric circles, the cellular zones between which are exceedingly loose, the ligneous tissue having the tubes marked by circular discs; the leaves are pinnate, not articulated, and have a gyrate venation. The flowers are dioecious; the male flowers are arranged in tessellated catkins with abrupt scales, the anthers oval, sessile at the under side of each scale. The female flowers are in tessellated catkins, the scales peltate, drupes two at the under side of each scale. The species are found in the tropics of America and Asia, and also at the Cape of Good Hope and in Australia.

Z. spiralis has numerous leaflets, linear, very smooth, somewhat curved, with a few spinous teeth at the extremity; the catkins smooth, with pointed scales in the female, and wedge-shaped ones in the male flowers. This plant is a native of New South Wales. The cone is about half the size of a man's head, and composed of nuts about the size of a chestnut. These nuts are eaten by the natives of Australia, but on being tried by English settlers produced sickness. Their flavour is not unlike that of chestnuts.

Z. cycadia, Bread-Tree Zamia, has lanceolate spinous smooth entire leaflets tapering at the base; the scales of the catkins abrupt, obtuse, pointless. It is a native of the south-eastern parts of southern Africa. The stem is thick and scaly, and attains a height of six or seven feet. Thunberg states that when the stems become old they are broken through by the Kaffres and Hottentots, who collect the pith and tie it up in the skin of a sheep or calf which has been previously well rubbed with grease. It is then buried in the ground, and after remaining there till it becomes putrefied, it is taken up and bruised between two stones, and then formed into little cakes about an inch in thickness. These are baked in wood-ashes, and are esteemed by those who prepare them as a great luxury, though they are not at all palatable to a European taste.

About seventeen species of the old genus *Zamia* have been described. Eight of these are now placed in the genus or sub-genus *Arthrozamia*, which is characterised by having the leaflets articulated with the rachis of the frond-like midrib; there is also a preparation in the rudimentary stamen to form a 2-celled anther, while in *Zamia* the leaflets are confluent, and the pollen is not disposed in 2-lobed masses. A fine collection of these plants exists in the Royal Gardens at Kew, and another has been made by Mr. Yates at Lauderdale House, Highgate.

The genus *Zamia* has many representatives in a fossil state. Of the sixteen species that have been discovered, twelve resemble so nearly the recent species that they have received the same designation. The remaining four differ in the exsertion and venation of their leaves, and hence they are placed under the fossil genus *Zamites*. The principal forms of these genera have been found in the lias and oolitic formations. Two fossil stems nearly resembling those of *Zamia* were found by Dr. Buckland in Portland stone. These are made by Brongniart to constitute the genus *Mantellia*, a name given in honour of Dr. Gideon

Mantell. He has also included in the same genus a stem found in shelly limestone near Luneville.

ZAMITES, a genus of Fossil Cycadeous Plants from the Oolitic, Wealden, and Cretaceous formations (Presl), synonymous with *Mantellia* and *Brongniart*.

ZANELOSTOMUS. [*CUCULIDÆ*.]

ZANNICHELLIA, a genus of Plants belonging to the natural order *Naiadaceæ*, named after John Jerome Zannichelli, a botanist. The flowers in this genus are monœcious. The male flowers have neither calyx nor corolla, with a single elongated filament surmounted by an oblong anther; the female flowers have a calyx consisting of a single leaf, no corolla, the germen four or more, the stigmas peltate, and the capsules sessile.

There is but one species of this genus, *Z. palustris*, the Marsh Horned-Pondweed. It is a native of ponds, ditches, and rivulets in most parts of Europe.

ZANO'NIA, a genus of Plants belonging to the natural order *Cucurbitaceæ*, named after James Zanoni. The only species belonging to this genus is *Z. Indica*, the Climbing Indian Cucumber. The fruit is described by Rheede as obscurely triangular, and having the flavour of the cucumber.

ZANTHOMIZA. [*XANTHOMYZA*.]

ZANTHORNUS. [*STURNIDÆ*.]

ZAPORNIA, Leach, a genus of Birds belonging to the family *Rallidæ*. The beak is slender, shorter than the head, acuminate, compressed, acute; upper mandible gradually incurved; nostrils linear, lateral, placed at the base of the beak. Legs long, slender, cleft, with three toes in front; the hinder toe elevated from the ground at its base; the tibia half naked. (Gould.)

Z. porzana, the Spotted Crane. This is the Petit Rale d'Eau, Caouchouan, and Marouette of the French; Porcellana, Porzana, Grugnetto, Porciglione, and Gallinella, of the Italians; Punktiertes Rohrhuhn and Kleines Gesprenkeltes Wasserhuhn, of the Germans; Speckled Water-Hen and Skitty, of the English; and Dwfrïar Fannog of the Welsh.

Adult and Old Male.—Forehead, eyebrows, and throat leaden-gray; sides of the head ash marked with black; upper parts olive-brown, but all the feathers black in the centre and variegated with small spots and stripes of pure white; breast and lower parts olive, shaded with ash and marked with white spots—these spots are rounded on the breast, but disposed on the sides in transverse bands; middle tail-feathers bordered with white; lower tail-coverts pure white; bill greenish-yellow, red at the base; feet greenish-yellow; iris brown. Length about 9 inches.

Adult Female.—Ash-colour of the throat and neck less extensive; sides of the head with brown spots; base of the bill with rather less red.

It is found in Sweden (summer visitor, rare); Southern Russia; north of Germany and Holland (rare); France, Provence, and to the Mediterranean (more common). It is of most frequent occurrence in the south and east of Europe; it has been seen at Smyrna in the winter, and is stated to extend to India. It is a summer visitor in

England, Scotland, and Wales, but is not common; and is occasionally found in Ireland in the summer.

Although the Spotted Crane is not common in these islands, there is no doubt that it breeds here, the eggs and young having been found in the Norfolk marshes and in other localities. Mr. Selby, accompanied by a shrewd dog that was up to their tricks, sometimes flushed as many as six in the large Northumbrian morass in his neighbourhood, just before their autumnal migration, and the majority were young birds of the year.

The fine flavour of this bird is well known and appreciated in France. Few, if any, of the aquatic, or indeed of any tripe, can match it in autumn as a rich morsel for the table, especially if it be young. Colonel Hawker, speaking of the Common Water-Rail and this species, truly says, "Notwithstanding these two are seldom regarded by sportsmen, yet there is scarcely a greater delicacy than either the one or the other." Both are indeed first-rate, but the Spotted Crane for choice.

Spotted Crane (*Zapornia porzana*).

There are two other European and British *Zapornia*, namely, the Little Crane, or Olivaceous Gallinule (*Zapornia pusilla*), and Baillon's Crane (*Z. Baillonii*); of both these M. Temminck says that the specimens found in Japan are the same with those killed in Europe.

ZEA, a genus of Plants belonging to the natural order *Graminaceae*. The name is identical with the Greek *Zeid*, but the Greek plant was a species of *Triticum* or *Hordeum*, and not at all agreeing with the present genus, which is entirely American.

The plants belonging to this genus are monœcious. The male flowers are in distinct spikes; the calyx consists of a 2-flowered blunt glume; the corolla of a blunt glume. In the female flowers the calyx is a 2-valved glume; also the corolla; the style is single, filiform, pendulous; the seeds solitary, immersed in an oblong receptacle. There are two species.

Z. Mays, Common Maize, or Indian Corn, which is known by its entire leaves. It is a native of America, and is cultivated there, as in most countries of Southern Europe. Like the species of *Triticum*, those of this genus present almost innumerable varieties, from the cultivation to which they have been submitted. As an article of food the fruit is much inferior to that of the *Triticum*, nor will it ripen its fruit fully in high northern latitudes.

Z. Curagua, Chili Maize, or Valparaiso Corn, is distinguished by its serrated leaves. It is a smaller plant in all its parts than the foregoing, and is a native of Chili. A sort of religious reputation is attached to this plant on account of the grain when roasted splitting into the form of a cross. [MAIZE, in ARTS and SC. DIV.]

ZEAGONITE, a Mineral identical with *Phillipsite*. [PHILLIPSITE.]

ZEBRA. [EQUIDE.]

ZEBU. [BOVIDÆ.]

ZEDOARY. [CURCUMA.]

ZEMNL. [MURIDÆ.]

ZENAIIDA. [COLUMBIDÆ.]

ZENIK. [VIVERRIDÆ.]

ZEOLITES, a family of Minerals, so named because the species

generally melt and intumescere before the blow-pipe, the term being derived from the Greek *ζέω*, to boil. They consist essentially of silica, alumina, and some alkali, with more or less water. The most of them gelatinise in acids, owing to the separation of the silica in a gelatinous state.

They occur filling cavities in rocks, constituting narrow seams, or implanted on the surface, and rarely in imbedded crystals; and never disseminated through the body of a rock, like crystals of garnet or tourmaline. All occur in amygdaloid, and some of them occasionally in granite or gneiss. *Heulandite*, *Laumontite*, *Apophyllite*, and *Stilbite* have a strong pearly cleavage, and do not occur in fine fibrous crystallisations; when columnar, the structure is thin lamellar. Excepting *Laumontite*, these species dissolve in the strong acids, but do not gelatinise. The species *Natrolite*, *Scolecite*, *Stellite*, and *Thomsonite*, are often fibrous, and the crystallisations generally slender. The remaining species, *Harmotome*, *Analcime*, *Sodalite*, *Hawyne*, *Lapis-Lazuli*, and *Chabasite*, occur in short or stout glassy crystals, and are seldom fibrous. These minerals are described under their proper names.

(Dana, *Manual of Mineralogy*.)

ZERDA. [VULPES.]

ZEUGLON. [CETACEA.]

ZEUS, a genus of Fishes belonging to the family *Scomberidae*. The Boar-Fish of English writers is referred by Jenyns and others to this genus, but Cuvier, Lacépède, and Yarrell refer it to *Capros*. [CAPROS.]

ZEUXITE. [PREHNITE.]

ZEUZERA, a genus of nocturnal *Lepidoptera*. The male antennæ are furnished at the base with a double row of teeth, which are terminated by a thread: those of the female are single at the base.

Z. Esculi, the Wood-Leopard, is a rare species, of a white colour, with numerous steel-blue spots. The larvæ are found in the interior of decaying trees.

ZIBETH, or **ZIBET**. [VIVERRIDÆ.]

ZIMB, an Insect translated Hornet in Scripture (Exodus, chap. xxiii., ver. 28; Deut. vii. 20; Joshua xxiv. 12). The Hebrew name is 'tzirah,' and probably expresses its loud buzzing noise. The account which Bruce has given of the 'zimh,' or Dog-Fly, of Abyssinia, offers such striking analogies to the insect specifically termed 'tzirah,' and included in the more general term 'zehuh' of the Hebrew Scriptures, that very little doubt exists regarding the identity of the two. It is difficult to conceive that Isaiah could have had in view any other insect when he says—"The Lord shall hiss for the fly that is in the uttermost part of the rivers of Egypt" (Isaiah vii. 18). The original word rendered 'fly' in our translation is 'zebug,' and, as Bruce observes, "The Chaldee version is content with calling this animal simply 'zebugh,' which signifies the fly in general, as we express it in English. The Arabs call it 'zimh' in their translation, which has the same general signification. The Ethiopic translation calls it 'tsaltsalya,' which is the true name of the particular fly in Geer, and was the same in Hebrew." Bruce has given a graphic account of this fly, and there can be little doubt that this insect is related to the family of *Astridae*.

The Latin *Asilus* and the Greek *storpas* were probably only different pronunciations of the same term 'ha-tairah,' as this fly is called both by Moses and Joshua. Mr. Bracy Clark, in the 9th volume of the 'Linnæan Transactions,' part ii., 1843, refers the fly alluded to by Moses (and said to "hiss and make a noise") to *Æstrus bovis*, and remarks on Bruce's figure, that it has no resemblance to the genus of flies the *Cuterebra*, but is rather, though with something fictitious about it, allied to the genus *Stomoxys*, or perhaps *Tabanus*, both of which genera are certainly silent flies in their attacks on cattle.

There can be no doubt that the *storpas* was a perfectly distinct insect from any of the modern *Æstridae*.

(Kirby and Spence, *Introduction to Entomology*.)

ZINC. This metal, in commerce frequently called *Spelter*, was first mentioned by Paracelsus, in the 16th century, under the name of *Zindum*. It does not occur in the native state, but is obtained from its ores, which are chiefly the Sulphuret and Carbonate of Zinc.

Sulphuret of Zinc; *Blende*.—It occurs crystallised and massive. Its primary form is the cube. Cleavage parallel to the planes of the rhombic dodecahedron. Fracture conchoidal. Hardness: scratches carbonate of lime, and is scratched by phosphate of lime. Rather brittle. Colour white, and various shades of yellow, green, red, brown, and black. Streak varying with the colour from white to reddish-brown. Lustre adamantine. Transparent, translucent, opaque. Specific gravity 4.07. Massive varieties amorphous; structure crystalline, granular, compact, globular, botryoidal, reniform, stalactitic, fibrous. Before the blow-pipe it does not melt per se; but when heated on charcoal, fumes of oxide of zinc form a white coating upon it. When nearly or quite pure, it forms a colourless solution in nitric acid with the separation of sulphur. It is found in great abundance in many countries, both in primary and secondary formations, and both in veins and beds. It abounds in Cornwall and several of the northern counties of England: the white variety occurs in New Jersey, North America. Large quantities of the ores of zinc are met with and worked in Germany; they occur also in various other parts of the earth. It contains—

Sulphur	33.66
Zinc	66.34

Some varieties contain small portions of iron and cadmium.

Oxysulphuret of Zinc; *Voltzite*.—It occurs in the form of small hemispheres, which are divisible into thin layers. Fracture conchoidal, irregular. Hardness 4.5. Colour yellowish-red, interspersed with brown bands. Lustre pearly on the natural layers, but vitreous or resinous in the other directions. Slightly translucent, opaque. Specific gravity 3.66. It occurs in Cornwall (?), and at Roziers, department of Puy-de-Dôme, France. Analysis by M. Fournet:—

Sulphuret of Zinc	81.0
Oxide of Zinc	15.0
Oxide of Iron	1.8
Organic Matter	2.2
	—100

Carbonate of Zinc; *Calamine*.—It occurs crystallised and massive. Its primary form is a rhomboid. Cleavage parallel to the primary planes. Fracture uneven, conchoidal. Hardness: scratches fluor-spar, but is scratched by apatite. Colour white, yellowish-white, gray, brown, and green. Streak white. Lustre vitreous. Translucent. Opaque. Specific gravity 4.442. Massive varieties amorphous; structure granular, compact, reniform, botryoidal, stalactitic; fibrous. This ore occurs rather abundantly, and is found both in veins and beds in various parts of England, France, and in America. Analysis by Smithsonian, (1) from Somersetshire, (2) from Derbysbire:—

	(1)	(2)
Carbonic Acid	35.2	34.8
Oxide of Zinc	64.8	65.2
	—100	—100

Soluble, with the extrication of carbonic acid gas, in acids.

Hydrous Carbonate of Zinc; *Hydrous Calamine*.—It occurs usually massive or incrusting other minerals. Texture fine-grained and close. Hardness 2 to 2.5. Colour white or grayish or yellowish-white. Dull; opaque. Specific gravity 3.584 to 3.598. It frequently accompanies the preceding species. It is soluble in acids with the extrication of carbonic acid gas. It contains:—

Carbonic Acid	13.52
Oxide of Zinc	69.36
Water	15.10
	—97.98

Sulphate of Zinc; *Listerite*.—It occurs crystallised and massive. Primary form a right rhombic prism. Fracture conchoidal. Hardness 2.0 to 2.5. Brittle. Colour white, sometimes inclining to peach-blossom-red and violet-blue. Streak white. Transparent; translucent. Lustre vitreous. Specific gravity 2.036. Soluble in water. Taste astringent, nauseous, and metallic. Massive varieties amorphous; structure granular, compact, botryoidal, reniform, stalactitic, fibrous; sometimes investing other bodies. Before the blow-pipe froths, and covers the charcoal with white flocks. It is found at Holywell in Flintshire, Fahlun in Sweden, at Rammelsberg in the Harz, and Schemnitz in Hungary.

Beudant's analysis of the substance from Schemnitz, gives:—

Sulphuric Acid	29.8
Oxide of Zinc	28.5
Oxide of Manganese	0.7
Oxide of Iron	0.4
Water	40.8
	—100.2

Phosphate (?) of Zinc; *Hopeite*.—It occurs crystallised. Primary form a right rhombic prism. Cleavage parallel to the great diagonal, distinct. Fracture uneven. Hardness, scratches gypsum, is scratched by fluor-spar. Colour white, grayish-white. Streak white. Lustre vitreous, pearly on the cleavage plane. Transparent; translucent. Specific gravity 2.46. Before the blow-pipe yields water, but no carbonic acid; becomes milk-white, and melts into a clear colourless glass. Soluble without effervescence in nitric or hydrochloric acid, and slowly in sulphuric acid. It has been found hitherto only in the calamine-mines of Altenberg, near Aix-la-Chapelle. It consists of oxide of zinc, a little cadmium, an earth, and much water, probably combined with phosphoric acid.

Silicate of Zinc; *Willemite*.—It occurs crystallised and massive. Primary form an obtuse rhomboid. Cleavage easy, in a direction perpendicular to the axis. Transverse fracture conchoidal. Hardness, readily scratches glass and phosphate of lime; is scratched by the knife. Colour usually yellow, brownish, or reddish-yellow, sometimes white and transparent. Specific gravity 4.18. Before the blow-pipe, the crystals partly lose their transparency; with borax, a globule is obtained, which is transparent, with a small nucleus of silica floating in it. It is found at Moresnet, Aix-la-Chapelle, and contains:—

Silica	72.33
Oxide of Zinc	27.67
	—100

Hydrous Silicate of Zinc; *Smithsonite*; *Electric Calamine*.—It occurs crystallised in attached and globular and botryoidal aggregations of crystals. Primary form a right rhombic prism. Cleavage parallel to the lateral planes. Fracture conchoidal, uneven. Hardness, scratches fluor-spar, and is scratched by felspar. Brittle. Colour white, blue, green, yellow, and brown. Streak white. It becomes

electric by beat. Lustre vitreous. Transparent; translucent. Specific gravity 3.379. When beaten in a glass-tube yields water, and becomes milk-white. When heated before the blow-pipe with borax, it dissolves into a colourless glass, which does not become milky on cooling. When powdered and heated in hydrochloric acid, the oxide of zinc is dissolved, and the silica gelatinises on cooling. It is found at Matlock in Derbyshire, and other parts of England; in Scotland, Germany, and many other parts of Europe. It contains:—

	Smithson.	Berthier.
Silica	25.0	25.0
Oxide of Zinc	68.3	66.0
Water	4.4	9.0
	—97.7	—100

Aluminate of Zinc; *Automalite*. [GAHNITE.]

Oxide of Zinc and Oxide of Manganese; Red Oxide of Zinc; *Spartalite*. It occurs in imbedded small nodules and massive. Cleavage parallel to all the planes of a regular hexagonal prism. Fracture conchoidal. Hardness 4 to 4.5, easily scratched by the knife. Brittle. Colour bright-red. Streak orange-yellow. Lustre adamantine. Translucent. Specific gravity 5.4 to 5.5. Massive varieties amorphous, structure crystalline, granular. Before the blow-pipe infusible per se; but with borax gives a yellow transparent glass. In nitric acid dissolves without effervescence. It is found only in New Jersey, North America. It contains:—

Oxide of Zinc	88
Sesqui-Oxide of Manganese	12
	—100

Sulphuret of Zinc and Iron; *Marmatite*.—This is a definite compound of sulphuret of zinc and of sulphuret of iron; its structure is lamellar, and colour black; indeed it appears to be black blende united with sulphuret of iron. It is found at Marmato, province of Popayan, South America. It contains silica, which is a mere accidental admixture.

Bi-Seleniuret of Zinc and Protosulphuret of Mercury; *Riolite*.—It occurs massive. Structure granular. Lustre metallic. Colour light-gray. Opaque. Specific gravity 5.56. Before the blow-pipe burns with a fine violet-coloured flame, and exhales a strong smell resembling that of decayed cabbage. When beaten in a retort, selenium, mercury, and a little sulphur sublime, and there remains oxide of zinc, which is readily dissolved by acids. It contains lime, which must be considered as an accidental impurity.

Bi-Seleniuret of Zinc and Bi-Sulphuret of Mercury; *Culebritite*.—It occurs massive. Fracture earthy. Dull. Colour dull-red. Specific gravity 5.66. It is found at Culebras, Mexico.

Oxide of Zinc, Oxide of Iron, and Oxide of Manganese; *Tephroite*. It occurs massive. Compact. Cleavage perfect in several directions, two of them meeting at right angles. Fracture uneven. Hardness 5 to 6. Lustre adamantine. Colour ash-gray, tarnishing black. Streak paler. Specific gravity 4.10. Before the blow-pipe it forms a black slag. It occurs with *Franklinite* and *Spartalite* at Sparta, United States.

ZINC SPAR. [ZINC.]

ZINGIBER. [ZINGIBERACEÆ.]

ZINGIBERACEÆ, *Gingerworts*, a natural order of Endogenous Plants. The plants belonging to this order are herbaceous, possessing a creeping and often jointed rhizoma. Their stem is formed of the cohering bases of the leaves, and is never branched. The leaves are simple and sheathing, the blade being often separated from the sheath by a taper neck; they have a single midrib, from which diverge at an acute angle numerous simple crowded veins. The flowers are arranged in a dense spike or raceme, or a sort of panicle, which is either terminal or radical. The flowers are supplied with spathaceous membranous bracts, which usually lie in pairs. The calyx is superior, tubular, 3-lobed, short. The corolla is tubular, irregular, with six segments in two whorls; the outer whorl is 3-parted, nearly equal; the inner is also 3-parted, and represents three stamens, the intermediate segment is larger than the rest, and called the labellum, and is often 3-lobed; the lateral segment is sometimes nearly abortive. The stamens are three, distinct, of which the two lateral are abortive, and the intermediate one fertile; this is placed opposite the labellum, and arises from the base of the intermediate segment of the outer series of the corolla; the filament is not petaloid, and often extends itself beyond the anther in the shape of a lobed or entire appendage; the anther is 2-celled, and opens longitudinally, the lobes often embracing the upper part of the style. The pollen is light, granular, globose, and smooth. The ovary is 3-celled; the ovules attached to a placenta in the axis; the style filiform, and the stigma dilated and hollow. The fruit is usually a 3-celled capsule, and sometimes from abortion 1-celled. The seeds are roundish or regularly angled, and sometimes with an aril; the albumen flowery; the embryo inclosed within a peculiar membrane called Vitellus, and Membrane of the Amnios by Brown.

This order of plants has been mostly placed with *Marantaceæ*. It was first constituted by Brown, who pointed out the difference between it and *Marantaceæ*. The distinguishing characters of *Zingiberaceæ* are—first, the structure of the seed, in which a fleshy body is interposed between the embryo and the albumen, entirely enveloping

the former. This body is called Vitellus by Brown, and is the remains of the innermost integument of the ovule, which is unabsorbed during the progress of the seed to maturity. A second peculiarity consists in the 2-celled anthers; and with this structure is combined decidedly aromatic properties. But the distinction between *Marantaceæ* and *Zingiberaceæ* depends, as pointed out by Lindley, on more important considerations than these. "In true *Zingiberaceæ*," he says, "as Brown has observed, the stamen is always placed opposite the labellum, or anterior division of the inner series of the corolla, and proceeds from the base of the posterior outer division; while the sterile stamens, when they exist, are stationed right and left of the labellum. But in *Marantaceæ* the fertile stamen is on one side of the labellum, occupying the place of one of the lateral sterile stamens of *Zingiberaceæ*. This peculiarity of arrangement indicates a higher degree of irregularity in *Marantaceæ* than in *Zingiberaceæ*, which also extends to the other parts of the flower." It contains 29 genera and 247 species.

Nearly all the species are tropical plants, and by far the greater number inhabit various parts of the East Indies; they are also found in Africa and America.

The plants belonging to this order possess great beauty, on account of the development of their floral envelopes and the rich colours of their bracts. They are also employed to a considerable extent in medicine and as condiments, on account of their aromatic stimulating properties. [CURCUMA; AMOMUM; ALPINIA.]

Zingiber is known from the other genera by the inner limbs of the corolla having but one lip, and the anther having a simple recurved horn at the end.

Z. officinalis, the Narrow-Leaved, or Common Ginger, has subsessile, linear-lanceolate, smooth leaves, elevated oblong spikes, acute bracts, and a 3-lobed lip. The root-stock of this plant is the ginger of commerce. It is imported into England from various quarters of the world, but more especially the East and West Indies. This plant is now grown in almost all parts of the globe in tropical climates, but it seems to have been originally indigenous in the East Indies. [GINGER, in ARTS AND SC. DIV.]

Zingiber officinalis.

1, plant, showing the rhizoma and inflorescence; 2, flower separated, showing epatheaceous bracts; 3, the perfect 2-celled anther with styles.

Ginger is one of the most agreeable of the hot aromatics, and is consequently much used as a condiment. It also enters into the composition of many medicines, where it acts as a carminative.

Z. Zerumbet, the Broad-Leaved Ginger, is a native of the East Indies, and has delicate stems; bifarious, sessile, lanceolate leaves; broad obovate bracts, and a 3-lobed lip. This plant is much used in the east for cataplasms and fomentations, but is not taken internally.

ZINKENITE. [ANTIMONY.]

ZINNIA, a genus of Plants belonging to the natural order *Compositæ*, named after Dr. John Godfrey Zinn. It has a chaffy receptacle, the seed-down consists of two erect unequal awns, the calyx imbricated, somewhat ovate, the florets of the radius 5-10, permanent and undivided. All the species are natives of South and North America; they are annuals, and form handsome border-plants in gardens. They resemble *Rudbeckia*.

ZIPHILUS. [CETACEA.]

ZIRCON—*Hyacinth*; *Jargoon*—a Mineral occurring in attached, imbedded, and loose crystals. Primary form a square prism. Cleavage parallel to the lateral planes, indistinct. Fracture conchoidal, undulating, brilliant. Hardness, scratches quartz. Brittle. Colour white,

gray, red, reddish-brown, brownish-orange, yellow, pale-green; streak white. Lustre adamantine. Doubly refractive in a very high degree. Transparent; translucent; opaque. Specific gravity 4.505. Before the blow-pipe infusible, but loses its colour; with borax fuses into a transparent glass. It is found at Expailly, in France; Ceylon; at Friedrichsuarn, Norway; Greenland, the United States, &c. It contains—

Silica	33.3
Zirconia	66.7

—[TITANIUM.] —100

ZIRCONIA. [ZIRCONIUM.]

ZIRCONIUM, a peculiar Metal obtained from the earth or metallic oxide zirconia. [ZIRCON.]

ZIZA'NIA, the Greek name of *Lolium temulentum*, the modern Darnel. This plant has always been troublesome amongst wheat, and is mentioned in the New Testament, and in the English version *Zizanium* is translated 'Tares.' The name has now been adopted by Gronovius and Linnaeus for a very different genus of *Graminaceæ*. It is monœcious; the male flowers have no calyx, and their corolla is a 2-valved blunt glume, which are mixed with the female flowers; the female flowers have no calyx, and their corolla is a 2-valved glume, cucullate, and awned; the style is 2-parted; the seed single, enveloped in the plaited corolla.

Z. aquatica is the Canadian Wild-Rice. It has a pyramidal compound panicle, with numerous male flowers in the lower part; spiked and female above. This plant is common in all the waters of North America from Canada to Florida. It flowers in July and August, and is known by the name of *Tuscarora*, or Wild Rice. It was introduced into this country by Sir Joseph Banks, in 1793, who cultivated it for many years in the ponds of his villa at Spring Grove. The seeds of this plant afford a nutritious article of diet, and are eaten by the wandering tribes of North-West America. The water-fowl of North America also feed on the grains of this plant.

ZIZYPHIUS, Ζίζυφος, a genus of Plants belonging to the natural order *Rhamnaceæ*. It has a 5-cleft spreading calyx; 5 obovate unguculate convolute petals; a pentagonal flat disc, expanded and adhering to the tube of the calyx; a 2-3-celled ovary immersed in the disc; the styles 2-3; the fruit fleshy, containing a 1-2-celled nut; the seeds sessile, compressed, and very smooth. The species of this genus are shrubs, with alternate 3-veined leaves, spiny stipules, and mucilaginous fruit, which is eatable.

Z. vulgaris, the Common Jujube, has ovate-retuse toothed smooth leaves; prickles absent or twin; and an ovate-oblong drupe. This plant is a native of Syria, whence it has been introduced into Europe. It is now cultivated in many parts of the south of Europe, where its fruit is known by the name of Jujube. It has yellow-greenish flowers, two or three of which grow together. The fruit is of a blood-red or saffron colour, and has a sweet granular pulp. In Italy and Spain it is eaten as a dessert when fresh, and in the winter season as a dry sweetmeat. It is also sold in great quantities in the markets of Constantinople. The Jujube is commonly planted by the Turks of Constantinople before their coffee-houses for the sake of its shade.

Z. Spina-Christi, Christ's Thorn, has ovate-toothed smooth leaves, pubescent beneath; prickles twin, one straight, the other incurved; the peduncles corymbose; the drupe ovate-globose. This plant is about eight feet high, and is a native of the north of Africa of Palestine, Ethiopia, and Egypt. The flowers are yellowish-green. The fruit is oblong, about the size of a sloe, and much eaten in Egypt and Arabia. This plant has plant branches, and is covered with thorns; and being not uncommon in Palestine, has been supposed by Hasselquist to have afforded materials for the crown of thorns with which Jesus Christ was crowned. The *Paliurus aculeatus* however is the more common thorny plant in that country. [XALLÆ.]

About 40 other species of *Zizyphus* have been described; amongst them the *Z. lotus*, which is the Lotus of the ancients. [LOTUS.] Many of them are natives of the Himalayas. Wherever they grow, they produce a fruit which may be eaten with impunity, although it varies much in its grateful and nutritious properties. *Z. Napaea* grows in Ceylon; *Z. xylophorus*, in Coromandel; and *Z. Jujuba* in China, yields edible fruits.

ZOANTHARIA ('Animal Flowers,' from the Greek ζῷον and ἄνθος), the third class of true Zoophytes, in the arrangement of De Blainville, and defined by him thus:—"Body regular, flower-shaped, more or less elongated, free or fixed, very contractile, furnished with an intestinal canal, without distinct walls, having a single large terminal opening surrounded by variously-shaped tentacula, which are always tubular and in communication with the musculo-cavernous parenchyma of the skin." The terms of this definition are in part incorrect, there being no intestinal canal properly so called, but a large bag-shaped stomach having distinct walls, for a representation of which see ACTINIA.

The Zoantharia correspond to the Zoophyta *Helianthoida* of Dr. Johnston, and includes the sea-anemones and the greater number of the coral animals. The anatomical structure of the latter is essentially the same with that of the former, however different the aspect of the gorgeous madrepores of the Tropical seas may be from that of the soft and fleeting sea-flowers of the north. The beauty of the

creatures included in this order, and the important part they have played in the formation of the crust of the earth, have rendered them favourite objects of study with both zoologists and geologists, whilst the size to which they attain, greatly exceeding that of most other zoophytes, has enabled the anatomist to investigate their internal organisation in a very satisfactory manner. In the present state of our knowledge of their structure their essential characters may be summed up as follows:—Polypes separate or conjoined, free or attached, more or less cylindrical or expanded, mostly regular and circular, the parts arranged around a centre; mouth contractile at one extremity of the axis, opening into a large stomach capable of protrusion, terminating in a 'cul de sac,' and furnished laterally with longitudinal folds. Between the walls of the stomach and the epidermis are numerous muscular lamellae, and in the interspaces are the ovaries and (caecal?) filamental appendages. The mouth is surrounded by a disc, usually tentaculiferous (in some species the tentacula are obsolete). Tentacula simple or pinnate, bellow, their internal walls clothed with vibratile cilia, which also are found on the ovaries.

The state of the nervous system is still doubtful. Wagner has lately asserted the bi-sexuality of these zoophytes.

The posterior extremity of the body is in some species elongated and acute, in others it forms a suctorial disc; in a great number it secretes in its tissues calcareous matter, which is disposed in regular form, and constitutes the coral or polypidom, and in the group of Coriaceous *Zoantharia* expands into a leathery fixed crust, which forms a common base for several individuals.

The *Zoantharia* may be grouped under four very natural families, namely:—

I. *Lucernariade*, the animals included in which are soft and simple, fixed by a small base or free, and having the tentacula in groups at regular distances on the margin of a campanulate disc, in the centre of which is the mouth.

II. *Actiniade*: animals all soft and simple, fixed or free; when fixed, adhering by a broad base; the tentacula in most species developed and surrounding the margin of the oral disc.

III. *Zoanthide*: animals coriaceous, simple or compound, fixed; tentacula marginal, surrounding the mouth.

IV. *Madreporidae* (including the *Madrephyllicea* of De Blainville): animals forming a solid calcareous polypidom; in other respects they resemble the *Actiniade*.

Family I. *Lucernariade*.

The animals of this family belong to a single genus, that of *Lucernaria*, established by O. F. Müller. They are campanulate, and fixed to sea-weeds by a narrow disc or stalk, from which they expand into a broad octagonal disc, in the centre of which is a quadrangular mouth, and at each angle a bundle of tentacula. In the intermediate spaces are little coloured lobes, which have been regarded by some naturalists as organs of vision; surrounding the mouth festoons of ovaries are seen. All the species known are inhabitants of the British and Norwegian seas. The largest measure about an inch in height. They are of various colours, but usually pink. They swim with rapidity, by alternately dilating and contracting their bodies, but usually adhere to sea-weeds, where they feed on small *Crustacea*, which Lamoureux asserts they perceive in the water and endeavour to seize. Their habits have been observed by Otto Fabricius, Montagu, Flemming, and Dr. Johnston, whose work on British zoophytes contains a good account of the several species.

Although Cuvier, Blainville, Ehrenberg, and Johnston have all placed the *Lucernaria* among the fleshy polypes, some writers dissent from such an arrangement. M. Dujardin remarks, "We ought to draw a great distinction between the papilliform tubercles of the arms of *Lucernaria*, and the extensible tentacula of *Actinia*. Perhaps when the structure and quaternary arrangement of their ovaries, approaching that of the *Medusae*, are considered, they ought to be approximated to the latter type."

L. auricula is the best known species.

Lucernaria auricula.

Family II. *Actiniade*. [ACTINIADÆ.]

Family III. *Zoanthide*.

It comprises the following genera:—

Zoanthus, Cuvier.—The body is elongated, conic, and pedunculated, NAT. HIST. DIV. VOL. IV.

springing from a base common to several individuals. The mouth is linear and transverse, in the centre of a disc bordered by short slender tentacula.

Z. Couchii of Johnston is the only European representative of this family. It is found on the British coasts.

Mammilifera, Lesueur (*Polythoe*, Lamoureux).—The body is coriaceous, short, and mammiliform; slightly enlarged at its buccal extremity, and provided with several rows of marginal tentacula. It is sub-pedunculated at the base, and springs from a common expansion.

M. auriculata is a native of the West India Islands.

1, *Zoanthus Solanderi*; 2, *Corticifera glareola*; 3, *Mammilifera auriculata*.

Corticifera, Lesueur.—Body short, cylindrical, having a longitudinal mouth surrounded by petaliform tentacula at one extremity, and merged at the other into a common mass with numerous similar individuals, so that a solid poliferous crust is formed. Thus there is a transition through this genus from the soft *Actinice* to the Corals.

C. glareola is found in Guadeloupe.

The best account of the *Zoanthide*, with excellent figures, will be found in the papers of Lesueur, in the first volume of the 'Transactions of the Philadelphia Academy.'

Family IV. *Madreporidae*.

The animals which form the harder and larger corals closely resemble the *Actinice*. Generally, as far as they have been examined, there is but little variety among them; but judging from the differences presented by one or two types, it is probable that future researches will show a greater diversity of form in this family than is at present admitted. Thus, though the usual form of the coral animal is that of a cylinder terminated by a disc surrounded by simple tentacula, in *Fungia* we have the tentacula irregularly scattered over a broad expansion; and in *Desmophyllum* they are reduced to the appearance of irregular folds. [POLYPIFERA; MADREPHYLLICEA; MADREPORÆA; ASTRÆA.]

Animal of *Cladocora caespitosa*. (From an original drawing.)

ZOARCES, a genus of Fishes belonging to the family *Gobiada*. It has an elongated body, covered with a mucous secretion; the head

a smooth, muzzle blunt; ventral fins situated before the pectorals; dorsal, anal, and caudal fins united; all the fins very thick; vent anterior to the middle of the body, its situation marked by a tubercle; teeth conical, placed in a single row; branchiostegons rays six in number.

Z. viviparus, the Viviparous Blenny, differs from the other British Blennies in the circumstance to which its name refers—that of bringing forth its young alive, which seem perfectly able to provide for themselves the moment they are excluded. The ventral fins of this fish assume the appearance and perform the functions of the legs of higher animals. It is said to use these limbs for the purpose of climbing on the rocks out of the water, where it will remain exposed to the air for some time, thus forming an approach to the reptile forms of life. When boiled, the bones of this fish are green; hence its name of Greenbone.

ZOISITE. [EMIDOTE.]

ZONOTRICHIA (Swainson), a sub-genus of *Fringilla*. [FRINGILLIDÆ.]

ZONURIDÆ, a family of Saurian Reptiles possessing the following characters:—Head pyramidal or depressed, covered with regular many-sided shields. Tongue flat, nicked at the tip. Scales of the back and tail large, rhombic. Sides with a distinct longitudinal fold, covered with small granular scales. Ears distinct. Eyes with two valvular lids. Limbs four, strong, or rarely entirely wanting or hid under the skin.

The following is a synopsis of the genera from the British Museum Catalogue:—

A. Femoral pores distinct. Nasal shield without any or only one pair of supra-nasals. Legs four. Occipital shields few. It inhabits the Old World.

a. Tail spinose. Head depressed. Fronto-parietal and parietal plates forming a large square. Tongue velvet-like. Collar none, with a slight cross fold on the side of the neck. Femoral pores numerous.

Cordylus.—Scales of back and sides square, in close cross series. Lower eyelid transparent. Nasal small; supra-nasals square, contiguous.

Zonurus.—Scales of back and sides square, keeled, in close cross series. Lower eyelid opaque. Nasal triangular; supra-nasal none.

Hemicordylus.—Scales of back small, square, in cross rows; of the sides granular. Nasal triangular; supra-nasal none.

Pseudocordylus.—Scales of the back suboval, in cross rows, surrounded with granules, with a fold on each side of the neck. Nasal triangular; supra-nasal none.

b. Tail unarmed. Head pyramidal. Tongue scaly. Supra-nasal none.

Platysaurus.—Toes 5-5. Head depressed. Fronto-nasals two, fronto-parietals and parietals distinct, equal. Body fusiform.

Cicigna.—Toes 5-5. Head square. Fronto-nasals two, fronto-parietal and parietal united on each side. Body fusiform.

Gerrhosaurus.—Toes 5-5. Head square. Fronto-nasals two, fronto-parietals and parietals distinct, equal. Body fusiform.

Pleurostichus.—Toes 5-5. Head square. Fronto-nasals none, fronto-parietal and parietals equal. Body and tail elongate.

Sauropsis.—Toes 4-4, very short. Body and tail elongate.

Caitia.—Feet undivided, front very slender, elongated, hinder compressed, thick. Body and tail elongate. Femoral pores 2-2.

c. Tail unarmed. Head pyramidal, elongate. Collar distinct, of keeled scales. Inguinal pores 2-2.

Tachydromus.—Ventral shields keeled. Throat with keeled scales.

Tachysaurus.—Ventral shields smooth. Throat granular in front.

B. Femoral pores none. Nasal plates with two or more pairs of supra-nasal shields above. Occipital plates numerous. Collar none. Throat shielded.

a. Limbs four. Body fusiform. Tongue velvety. It inhabits the Western Hemisphere.

Abronia.—Head depressed. Inter-nasal small, distinct. Scales of back smooth.

Gerrhonotus.—Head pyramidal. Inter-nasal small, supra-nasal large. Scales of the back keeled.

Elgaria.—Head pyramidal. Inter-nasal large, supra-nasal very narrow. Scales of the back keeled, of sides smooth. Tail elongate, slender.

Basiliscus.—Head pyramidal. Inter-nasal plates none. Scales of back keeled.

b. Legs two or none. Body snake-like.

Pseudopus.—Limbs two, posterior, undivided.

Ophisaurus.—Limbs none.

A. Femoral pores distinct. Supra-nasal shields none or only one pair. Occipital shields few. Legs four. It inhabits the Eastern World.

a. Tail spinose. Head depressed, broad. Fronto-parietal and parietal plates large. Tongue velvet-like. Collar none, or only a slight fold on each side of throat. Nostrils in a single plate. Femoral pores numerous. [ZONURINÆ.]

We now proceed to give a few illustrations of the species of this family, of which thirty are described in the 'British Museum Catalogue.'

Zonurus griseus has the lower lid squamous and opaque. It is a native of the Cape of Good Hope and Senegal.

Zonurus griseus.

This is the *Cordylus griseus* of Cuvier, and the *Zonurus Cordylus* of Merrem.

Tachydromus scutellatus, the Tachydrome, is a tropical form of this family, and is found in Cochin-China, China, Borneo, and Java.

Tachydrome (*Tachydromus scutellatus*).

Pseudopus Pallasii, the Sheltopusik, or Scheltopusik, is the only species of *Pseudopus*. It is remarkable for the slight development of its extremities, as seen in the figure of the vertebra (a a). Cuvier classed this animal with the *Ophidia*, at the head of the *Orveta*; but there can be no doubt of its connection with the *Sauria*, and the nature of its vertebral development is interesting in relation to the

theory of the vertebrate nature of the limbs of the higher animals. [VERTEBRA.]

Pelvis of Scheltopusik, showing at *a a* the rudiments of the posterior extremities.

Scheltopusik (*Pseudopus Pallasii*).

Saurophis tetradactylus is the *Tetradactylus Chalcidius* of Merrem, *Lacerta tetradactyla* of Lacépède, and *Saurophis Seps* of Fitzinger. It is a native of the southern point of the African continent.

Saurophis tetradactylus.

The genus *Chamaesaura* approaches the *Zonuridae*, but Dr. J. E. Gray has constructed for this genus a distinct family, with the following characters:—

Chamaesauri (*Chamaesauridae*).—Head covered with regular many-sided shields; tongue nicked; palate toothless; temple scaled like the back; eyelids distinct, lower scaly. Body subcylindrical, clougate, the whole except the head covered with rings of elongate keeled scales, forming longitudinal series; limbs rudimentary. Ears distinct, small; no lateral groove; sides rounded, covered with scales like the back. It is a native of Africa.

The only genus and species is the *Chamaesaura anguina*, the Anguine Lizard. It is the *Lacerta anguina* of Linnaeus, and is an inhabitant of the Cape of Good Hope.

Anguine Lizard (*Chamaesaura anguina*).

It is interesting to trace in the Saurians the gradual deterioration and abolition of the extremities till the form becomes completely serpentine. In *Heterodactylus* there are still five fingers; but the first finger of the anterior feet is so very short as to be rudimentary. In *Chalcis* (*Cophias*, Fitzinger) there are five toes before, but only three, reduced to tubercles, behind. In *Saurophis* the toes on each of the feet are reduced to four. In *Chamaesaura* there is but one on each foot. In *Chirotes* the anterior extremities are short indeed, but 5-toed; the posterior extremities are altogether absent. In *Bipes* the hind feet are each terminated by two unequal processes or toes. In *Pygopus* the anterior extremities are also lost, and the posterior extremities appear in the form of a foot in which no toe is to be seen externally; and in the Scheltopusiks all trace of external extremities is lost, though the rudiments of posterior extremities may be seen attached to the pelvis. [CHALCIDES; CHIROTES; BIPES.]

ZONURUS. [ZONURIDÆ.]

ZOOCARPES, a group of Cryptogamic Plants, so named on account of the locomotive character of their spores. [ALGÆ; DIATOMACEÆ; DESMIDÆ.]

ZOO'PHYTA (from ζῷον, animal, and φυτόν, plant). This is the title most generally employed for the Radiated and Phytoid forms of animal life, included by Linnaeus in his great divisions of *Vermes*, namely, *V. Mollusca*, *V. Lithophyta*, and *V. Zoophyta*. Under this title Cuvier ranked the Intestinal Worms, which are more analogous to *Annulosa*; and most writers include Sponges and Corallines, which others rank with plants. [POLYPIFERA; POLYZOA.]

ZOOTOCA, a genus of terrestrial *Sauria*, nearly allied to *Lacerta*. Both these genera are described in the article SAURIA. As they have both of them British representatives we here present engravings of them.

Head of *Lacerta*, seen from above. (Bell.)*Lacerta agilis*.*Lacerta vivipara*.

For a full account of these creatures see Professor Bell's interesting 'History of British Reptiles.'

Professor Owen ('Trans. Geol. Soc.') has described a fossil obtained from the Lower Chalk, which seems to have been closely allied to the existing small Lacertine Saurians.

Side view of portion of lower jaw of Lacertine reptile from the Lower Chalk near Cambridge.

ZOSTERACEÆ, *Sea Wracks*, a natural order of Endogenous Marine Plants, resembling sea-weeds, and living among them. The species have grassy thin leaves, sheathing at the base. The flowers are very

minute, absolutely naked, or surrounded by three scales. If we are to find anywhere a positive intercalation of flowering with flowerless plants, it is here, where, with naked flowers but distinct sexes, the pollen is in a condition that may be compared to the elaters of *Marchantia* and its allies, and totally different from all that is known of other flowering plants. The habit too is quite that of sea-weeds. The manner in which fertilisation takes place among these plants is unknown. The bottom of the ocean is their locality, and they occur from the North Sea to the Mediterranean, the Indian Ocean, and the coasts of Arabia. One species only is seen on the shores of Australia, and another in the West Indies.

Zostera marina, the Sea Wrack, is a British species, and is used as a common material for packing, and for stuffing cottagers' cushions; it has also been used medicinally as a poultice.

ZOSTEROPS, a genus of Insectivorous or Perching Birds, placed by Mr. Swainson in his sub-family *Paridae*. [SYLVIADÆ.]

The bill is rather stouter than in *Sylvicola*, acutely conic, almost entire. Rictus smooth. Wings moderate, pointed; the first quill rather shorter than the three next. Tail as in *Sylvicola*. Feet strong. Tarsus longer than the middle toe. Lateral toes unequal. Eyes encircled with compact white feathers. (Sw.) It is a native of India, Africa, America, and Australia.

Z. flava (Sw.), Yellow White-Eye, may be regarded as an example.

Yellow White-Eye (*Zosterops flava*).

Mr. Swainson, in his 'Birds of Western Africa,' observes that the species of this genus are all of small size, and nearly intermediate in their affinities between the Warblers and Titmice. He states his belief that only one species is found in the New World; the others, about twelve in number, being restricted to the warm latitudes of Asia, Africa, and Australia. One of these, *Zosterops curvirostris*, Swainson (*Dicaeum chloronotus* of the Paris Museum), has, he remarks, the bill nearly as much curved as some of the Honey-Suckers.

Mr. Swainson adds that the general plumage of all these hitherto discovered is green above and yellowish beneath; so that the species, otherwise well marked, possess a strong mutual resemblance in the general cast of their colours. He thus describes *Zosterops flava* :—

Size of *Zosterops dorsalis*, an Australian species, but the bill, which is black, is larger. The upper plumage is of a bright greenish-yellow, the under pure and bright yellow, uniform in all its parts; the quills and tail are blackish edged with yellow; the snow-white ring round the eye is very conspicuous, and it is connected to the base of the bill by a deep black line; the tail, although divaricated, is even, and the bill and feet blackish. Total length 4½ inches. (Sw.)

It is a native of Senegal.

ZOZYMUS (Leach), a genus of Brachyurous Crustacea, placed by M. Milne-Edwards in the division of Cryptopod Cancerians, between the genera *Carpilius* and *Lagostoma*.

Zozymus is hardly distinguishable except by the form of the claws, the extremity of which is enlarged and deeply hollowed out into a spoon-shape, a disposition which most influences the habits of the animal. It tends also, in his opinion, to establish the passage between the genera *Cancer* and *Xantho*; for he finds no character sufficiently precise to separate from it certain species, the general form of which is slightly less oval than that of the crabs properly so called, and the latero-posterior borders of whose carapace are nearly as long as the antero-posterior borders, which become strongly denticulated.

Z. aeneus has the carapace moderately large, convex, very unequal, strongly embossed, and nearly tuberculous at its posterior part; front slightly advanced and indistinctly divided into four lobes; latero-anterior borders of the carapace not prolonged beyond the level of the genital region, and armed with four very wide teeth, compressed

and united after the manner of a crest; anterior feet tubercular externally; the succeeding feet hollowed with furrows on their external surface. Length from about 2 to 3 inches: colour yellowish with reddish spots. It is found in the Indian Ocean.

cylindrical, and are four times as long as broad: the colouring matter is arranged in a triple irregular series of dots. This species is not so common as the others. When young it is of a dull pale green colour, and only three imperfectly spiral lines of globules are distinguishable,

Zozymus aneus.

ZURLITE, a Mineral occurring crystallised and massive. Primary form a cube or square prism. Cleavage indistinct. Colour asparagus-green, inclining to gray. Fracture conchoidal. Hardness about 6.0. Lustre resinous. Opaque. Specific gravity 3.27. Found on Vesuvius.

ZURNAPA, the Arabian name, according to Belon, of the Giraffe.

[GIRAFFA.]

ZUZARA. [ISOPODA.]

ZYGÆNA. [SQUALIDÆ.]

ZYGÆNIDÆ, a tribe of Insecta belonging to the order *Lepidoptera*, placed by Linnæus with the *Sphinges* on account of the resemblance of their antennæ to those of that family. Latreille divided them into two groups, according to the forms of the antennæ, which in the one are simple or scarcely pectinated, but are entirely so in the other, at least in the males. *Sesia* and *Zygæna* are examples of the former; *Procris* and *Aglaope*, of the latter.

The genus *Zygæna* includes some very beautiful insects, which, while they resemble moths in general aspect, fly during the day and in full sunshine. When at rest they deflex their wings. Their caterpillars have six feet, are pilose, and are not furnished with the corneous tubercle which those of the *Sphinges* bear on the last ring of the body. Unlike the last-named insects, they do not bury in the ground to undergo their metamorphosis, but spin a spindle-shaped cocoon of silky texture, which they attach to the stems and branches of grasses.

Zygæna filipendula, a greenish-black insect with six crimson spots on its upper wings, and red under-wings bordered with black, is a common British species.

ZYGNE'MA (from *ζυγον*, a yoke, and *νήμα*, a thread), a genus of Plants belonging to the family *Convolvaceæ*, of the natural order *Algae*. This genus is characterised in Hooker's 'British Flora' by the following structure:—The filaments simple, finally united by transverse tubes; the endochrome forming dotted spiral rings, which, after conjugation, are condensed into a globule in one of the filaments. Four species of this genus are described as British by Dr. Harvey, in the fifth volume of Smith's 'English Flora.' These are as follow:—

Z. nitidum, with dark-green filaments, parallelly joined, and the articulations with numerous arching spines. This is a very common species, and is found abundantly in our fresh-water ditches. "After conjugation," Mr. Harvey observes, "the filaments become crisped, fragile, and lose much of their lubricity; the spires are soon after decayed, and the contents of one articulation discharged through its tube into the opposite one, where they form a dark-coloured globule. The other species undergo similar changes."

Z. decimum, with dark-green filaments joined, in a parallel way, the spires doubly cruciate. This is also an extremely common species. Its joints are very variable in length. The granules, arranged in a spiral form, cross each other, so as to give them the appearance of the continued multiplication of the Roman numeral X, whence the specific name.

Z. quinum has pale yellow-green filaments, which are parallelly joined with simple spires. This is also a common species. The spiral lines in this species resemble the multiplication of the Roman numeral V.

Z. curvatum has green unbranched filaments, very slender, and here and there slightly bent, and combined by their angles; the joints are

These lines become afterwards more conspicuous, the rest of the filaments being nearly colourless, and their component granules larger. The threads or filaments unite here and there, but not at every joint, and the processes which connect the filaments together are not situated in the middle between the two joints. In some of the combined joints the contents appear unchanged, and in others they form a mass of larger granules than in the lines, and some have a large oval seed, which often swells the joints.

ZYGODA'CTYLI, the term used by M. Temminck, M. Vieillot, and others, to designate those perching birds which have their feet composed of two anterior and two posterior toes, the external toe of the two last mentioned being capable of a direction either forward or backward. The Parrots, Woodpeckers, Toucans, Cuckoos, &c., belong to this group, which forms the first tribe of the second order (*Sylviolæ*) of M. Vieillot, and the fifth order of M. Temminck.

ZYGOPHYLLACEÆ, *Bean Capers*, a natural order of Exogenous Plants. Seven genera are referred to this order, and the number of

Tribulus terrestris.

1, cutting, with leaves and flowers; 2, flower separated; 3, pistil deprived of calyx and corolla, showing the disc and glands; 4, section of fruit.

species is about one hundred. They are herbs, shrubs, and trees, having a very hard wood, and the branches often articulated at the joints. The leaves are opposite, and are furnished with stipules, are seldom single, mostly unequally pinnated, and without dots. The flowers are hermaphrodite, regular; the calyx is divided into 4 or 5 pieces, with a convolute aestivation; the petals are ungulate, alternate with the segments of the calyx, and a little longer; during aestivation they are very short and scale-like; the stamens are double the number of the petals, and dilated at the base, sometimes naked, sometimes placed on the back of a small scale and hypogynous; the ovary is simple, surrounded at the base with glands or a short spinous disc, more or less deeply furrowed with 4 or 5 cells; the ovules in each cell 2 or more, attached to the minor angle, pendulous or occasionally erect; the style is simple, usually with 4 or 5 furrows; the stigma is simple, or with 4 or 6 lobes; the fruit is capsular, sometimes fleshy, 4 or 5 angles or wings bursting by 4 or 5 valves bearing the dissepiments in the middle, or into as many close cells, and the sarcocarp not separable from the endocarp; the seeds are not so many in number as the ovules, and are either compressed and scabrous when dry, or ovate and smooth with a thin herbaceous integument; the embryo is green with a superior radicle, foliaceous cotyledon, and a whitish albumen of a horny and cartilaginous texture.

This order is nearly related to *Oxalidaceæ* and *Rutaceæ*, also with *Simarubaceæ* and *Elatinaceæ*.

The great bulk of the species are distributed throughout the temperate regions of the globe. The largest number are found in America, but the order has representatives in all the quarters of the Old World and in Australia.

The genus *Ehrenbergia*, named after Ehrenberg, the great microscopist, belongs to this order. It has only a single species, the *E. tribuloides*, which is an annual, bearing coppery vermilion-coloured flowers. *Zygophyllum*, the Bean Caper, is the most extensive genus of the order, comprising about twenty-seven species. *Z. simplex* is called in Arabia Garmal; it is esteemed a good remedy in diseases of the eyes, and the bruised leaves mixed with water are used for this purpose. *Z. Pabago*, Common Bean-Caper, is a common herbaceous perennial in our gardens, and was cultivated in Great Britain by Gerard as early as 1596. *Z. fatidum* gives out a strong fox-like scent, which renders the house in which it is grown very offensive, and on this account it is seldom grown. *Z. coccineum* is a native of the deserts of Egypt, and some parts of North America. The species of *Melanthus*, Mouey Flowers, are well known in our greenhouses and gardens.

THE END.
